Re: Comments Submitted on Behalf of the City of El Segundo
on the Supplement to the Draft EIS/EIR for the Proposed
LAX Master Plan Improvements

Dear Mr. Kessler and Mr. Ritchie:

Please accept the following comments on the July 2003 Federal Aviation Administration ("FAA") and Los Angeles World Airports ("LAWA") Supplement to the Draft Environmental Impact Statement/Environmental Impact Report ("Supplement") for the proposed Los Angeles International Airport ("LAX") Master Plan. These comments are submitted on behalf of the City of El Segundo. They consist of this letter, the attached reports prepared by expert technical consultants who have provided specialized analysis of certain areas of particular concern, and other attached documents referenced herein. The attachments submitted herewith provide additional relevant material which should be

SAL00015 V

David Kessler
Jim Ritchie
November 4, 2003
Page 2

carefully considered by you and the decisionmakers before taking any action on the proposed Master Plan. In addition, for convenience, appended to this letter are a table of contents and lists of attachments.

I. LAWA and the FAA Cannot Proceed Based on the 2003 Draft Master Plan Addendum and the Supplement to the Draft EIS/EIR Because the Documents are Legally Inadequate and Perpetuate Serious Flaws Previously Identified with Regard to the 2001 Master Plan and the Draft EIS/EIR.

Our review and the analysis by our expert consultants has identified errors, miscalculations, flawed methodology, and incorrect assumptions which, taken together, render the Supplement and the Draft EIS/EIR as a whole, inadequate under the California Environmental Quality Act ("CEQA") and National Environmental Policy Act ("NEPA"). Our comments cover the 2003 Draft Master Plan Addendum ("Addendum"), the Supplement, and the associated Appendices and Technical Reports. These documents fail to disclose the extent of the adverse environmental impacts of the Master Plan alternatives and, in particular Alternative D.

A fundamental issue, as set forth in Section II below, is the capacity of Alternative D. The capacity of the airport, in particular the number of passengers served, directly affects the levels of the environmental impacts of the airport, the most obvious being traffic congestion, air pollution, and noise. In asserting that Alternative D would serve no more than 78 million annual passengers ("MAP"), however, LAWA never conducted the gate capacity analysis necessary to determine the physical capacity of the airport configuration being proposed in Alternative D. Based on our own expert evaluation, a gate capacity analysis clearly demonstrates that the capacity of Alternative D significantly exceeds 78 MAP. The entire environmental analysis of the Supplement therefore hinges on an erroneous assumption regarding the number of passengers to be served under Alternative D, resulting in a serious understatement of the level of adverse impacts.

As set forth below in Section III, the analysis of adverse impacts continues to be inadequate in numerous other regards, which we discuss following the organization of the Supplement. As a preliminary matter, we have the following general comments regarding the analysis throughout the documents:

- The impacts discussions are improperly cut off at the year 2015, a mere twelve

years away. LAX causes significant regional environmental impacts on traffic, air quality, and noise in particular, and with the passage of time those areas continue to worsen. Cutting the analysis off at 2015 artificially reduces the full scope of impacts, resulting in a failure to disclose the true environmental impacts over the life of this project.

- The Supplement's descriptions of the particular elements of Alternative D and the No Action/No Project Alternative contain a number of inaccuracies, fail to provide key information and directly conflict with information in other LAWA documents. These problems are particularly pronounced with regard to the description of existing and proposed LAX cargo facilities.
- The Supplement relies on a problematic baseline for its analysis. As we explained in our comments on the Draft EIS/EIR, the 1996/97 baseline utilized in that document was improper because it ignored substantial development that took place at LAX after 1996/97. The Supplement properly acknowledges some of that development, including: Southern Airfield Complex taxiway improvements, terminal expansion/improvement projects, a new remote commuter terminal, remote aircraft parking and boarding facilities near the west end of LAX, and a new 989-stall parking structure. The Supplement improperly discounts those changes as "minor" modifications having no real impact on the airport's capacity. The document takes the position that the projects can therefore be added to the baseline without changing the results of the analysis in the EIS/EIR. This is incorrect. The projects at issue were undertaken as part of an overall effort by LAWA to increase the capacity of LAX, they were undertaken outside of the Master Plan process and without any of the necessary environmental review. As a result, there has been no public acknowledgment, much less mitigation, of the environmental impacts associated with those projects. This is unacceptable under CEQA and NEPA. LAWA and the FAA cannot, therefore, simply include the projects in the baseline. They must evaluate, acknowledge and mitigate for the impacts of those projects.
- The analysis fails to update information regarding cumulative impacts. In the years that have passed since the drafting of the Draft EIS/EIR, there have been changes in the cumulative and regional situation, in such areas as air quality, traffic congestion, etc., and new information is available and should be utilized regarding proposed projects and other cumulative conditions, which will have

impacts on local and regional environmental resources.

- Mitigation measures included in the Supplement are inadequate, as pointed out below and in our technical reports. In many instances mitigation is assumed or stated to be adequate without sufficient assurance of future funding. Unfunded improvements, especially of expensive roadway infrastructure, cannot be assumed to mitigate impacts. In other instances, mitigation measures suggested are unenforceable. Reliance by the Supplement on unfunded infrastructure and unenforceable mitigation results in a failure to disclose the true scope of the environmental impacts.
- With regard to the Southern Airfield, we are concerned that LAWA is improperly pursuing development of improvements outside of and segmented from the Master Plan process. The Southern Airfield improvements are a key component of the Alternative D proposal advanced as a means of addressing the problem of runway incursions on Runways 25L-8R and 25R-8L. LAWA's own documents indicate, however, that the agency has, in fact, already committed to undertaking the project. *See Attachment 11.* LAWA's significant and irrevocable commitment of resources to the southern runway complex modifications is wholly inappropriate. CEQA and NEPA require analysis, disclosure, and mitigation of impacts before such decisions.
- Similarly, we note that Los Angeles has already initiated the process to procure detailed airport engineering and design work for Alternative D, at a cost of millions of dollars in addition to the millions already spent. *See Attachment 17.* This raises two separate legal issues.
 - In much of the Supplement, there is an insufficient level of detail provided to fully disclose the environmental impacts and to design appropriate mitigation measures. The detailed subsequent planning must be carefully reviewed to ascertain whether it raises the need for additional environmental analysis.
 - The devotion by Los Angeles of significant sums of money to push forward Alternative D with detailed design review prior to completion of the CEQA/NEPA process would violate the requirement that a lead agency take no action that commits it to a course of action before the completion and

David Kessler
Jim Ritchie
November 4, 2003
Page 5

consideration of the final environmental analysis. Such funding would increase the momentum toward plan approval, and make it more difficult for decision makers, following a careful review of the environmental and other issues, to make changes in the plan or vote against its approval.

II. Master Plan Alternative D As Currently Proposed Would Expand LAX's Capacity Significantly Over 78 Million Annual Passengers.

One of LAWA's primary stated purposes in designing Master Plan Alternative D, as explained in the Addendum and the Supplement, was to address environmental concerns by developing an alternative with a capacity to serve no more than 78 million annual passengers (MAP), the capacity of the current airport (and therefore the No Action/No Project Alternative). The analysis in the Addendum and Supplement indicates that the capacity of Alternative D is 78.9 MAP, and the impacts analyses discussing the impacts of Alternative D rely on that basic assumption.

The issue of retaining the 78 MAP capacity of the airport is of such paramount importance that El Segundo retained an eminent expert in airport design and capacity to study the LAWA materials and provide an independent evaluation of the capacity of Alternative D. The report of Professor Adib Kanafani, *Capacity Analysis of Aircraft Gate Positions, Los Angeles International Airport Master Plan Alternative D*, is included as Appendix A to Attachment 7 to this letter.

Professor Kanafani concluded, after extensive review of LAWA's documents and personal communications with LAWA and its professional consultants, that LAWA did not conduct a capacity analysis of the proposed terminal and gate configuration. LAWA's assertion that Alternative D would serve no more than 78 MAP was based not on the physical ability of the gate configuration to serve passengers, but on market assumptions regarding the reactions of airlines and of the air transportation market to the configuration proposed in Alternative D. This analysis fails to reveal the actual physical capacity of the airport, and cannot be used as a representation of the capacity of Alternative D.

In fact, as LAWA's own documents show, Alternative D was designed to handle about the same number of aircraft operations in 2015 as Alternative C, which according to LAWA would serve 89 MAP (Table S3-1). The difference in the annual passenger projections calculated by LAWA for Alternatives C and D is based on

David Kessler
Jim Ritchie
November 4, 2003
Page 6

LAWA's assumptions that under Alternative D, the airlines would essentially fly smaller planes with fewer seats and fewer passengers. LAWA's conclusion that Alternative D would serve only 78 MAP is also the result of several inconsistent assumptions and erroneous calculations, which are identified in Professor Kanafani's report.

For example, LAWA's stated assumptions include a reduction in commuter flights under Alternative D (Addendum, section 3.3.3) as more of the demand for commuter service is met by other airports. However, in deriving its passenger projections, LAWA assumes *larger* numbers of small commuter planes under Alternative D. Addendum Table 3.3-1. Elsewhere LAWA uses an incorrect conversion factor to convert peak day operations to annual operations, a factor which is at odds with both current reality and LAWA's assumptions regarding future trends. LAWA's analysis also assumes the use of outdated aircraft and old seating configurations, rather than projecting the future use of aircraft currently on order by airlines.

In the absence of any actual gate capacity analysis by LAWA, Professor Kanafani undertook what LAWA did not provide, i.e. a calculation of the number of passengers that could be served at LAX under Alternative D, based on the proposed number and mix of types of gates. His analysis, set forth in full at Appendix A to Attachment 7, concludes that the true gate capacity of Alternative D exceeds the stated 78 MAP, and is conservatively estimated at about 87 MAP.

Professor Kanafani also analyzed the airfield improvements that are proposed under Alternative D, and concluded that based on those improvements alone the capacity of Alternative D was as high as, or higher than, that of Alternative C. As set forth more fully in Attachment 7, the extensions of the runways and other improvements to the airfield design all tend to enhance capacity by improving operations and reducing delays. Further, other aspects of the design of Alternative D, such as the terminal area and the parking provided, appear to be excessive for 78 million annual passengers and would accommodate more. Moreover, a review of LAWA's own tables regarding reductions in delays under Alternative D supports the conclusion that Alternative D would have a capacity similar to that of Alternative C.

In addition, as described in the Addendum and Supplement, the sequencing of airport improvements under Alternative D contains no assurances that current gate positions and other facilities would be decommissioned before new facilities come on line. This omission leaves the door open for the total number of usable gates to greatly

David Kessler
Jim Ritchie
November 4, 2003
Page 7

increase beyond what is analyzed in the Supplement. For example, the West Satellite Concourse is proposed for construction in Phase II, while the demolition of TBIT and conversion of the north terminal to linear facilities is in Phase III. In the period between completion of Phase II and the demolition called for in Phase III, the airport's capacity would substantially exceed the reported 2015 capacity.

In order for Alternative D to fulfill its stated purpose of retaining capacity at 78 MAP, significant revisions, including a reduction in the number of gates, would be required. LAWA should develop very specific phasing provisions to assure that actual capacity does not exceed 78 MAP, such as eliminating old gate positions before new gates become operational. Reduction of other facilities such as terminal space and excess parking should also be considered. Unless such revisions are incorporated into the airport plan, its capacity will far exceed the stated 78 MAP. Meanwhile, the environmental analysis of Alternative D, which is based on the stated capacity of 78 MAP, is inadequate under CEQA and NEPA in that it fails to provide public disclosure of the impacts of the actual capacity of the plan.

III. The Supplement to the Draft EIS/EIR Understates the Adverse Environmental Impacts of LAX Master Plan Alternative D and Fails In Numerous Other Ways to Satisfy Legal Requirements for Environmental Review.

On behalf of El Segundo, this firm previously submitted extensive comments on the Draft Master Plan and EIS/EIR circulated by LAWA and the FAA in 2001. *See* September 18, 2001 Comment Letter prepared by Shute, Mihaly & Weinberger LLP ("September 2001 Comment Letter"). Those comprehensive comments identified numerous fundamental flaws in both the plan and the environmental document. LAWA and the FAA have not yet released any response to those comments, and for the most part, the Supplement and Addendum ignore them.

The principle purpose of the Addendum and the Supplement appears to be the introduction and analysis of a new preferred Master Plan option: Alternative D. Additionally, the Addendum and the Supplement contain some additions and changes to the information and analysis in the 2001 Draft Master Plan and EIS/EIR. The Addendum and the Supplement do not, however, eliminate the problems identified in public comments on the 2001 Draft Master Plan and EIS/EIR. In fact, the Supplement's analysis generally perpetuates the same problems seen in the 2001 analysis. The comments

David Kessler
Jim Ritchie
November 4, 2003
Page 8

presented in our September 2001 Comment Letter regarding flaws in the environmental analysis of Alternatives A, B, C and the No Action/No Project Alternative, remain salient and apply to the Supplement's analysis of Alternative D. Therefore we incorporate those prior comments, as applicable to Alternative D, by this reference. We do not repeat prior comments in full here.

Simply stated, the Addendum and the Supplement, like the 2001 Draft EIS/EIR and Master Plan, fail to satisfy the legal requirement that LAWA and the FAA disclose the impacts of the proposed development. As detailed below, the documents are flawed in their basic design, methodology, analysis of impacts, and approach to mitigation. They misstate impacts, inflate project benefits and generally appear to be intended as advocacy documents in support of Alternative D. In short, they do not meet the requirements of CEQA and NEPA.

A. The Project Description is Fundamentally Flawed.

1. The Supplement to the Draft EIS/EIR Relies on a Problematic Baseline for its Analysis.

Our comments on the 2001 Draft EIS/EIR noted that the 1996/97 baseline utilized by LAWA and the FAA was inaccurate in that it did not include substantial development and changes that have taken place at LAX since 1996/97. *See* our September 2001 Comment Letter at 34-39. Apparently recognizing this problem, LAWA and the FAA have included some revised baseline information in the Supplement. *See* Supplement at 3-5, Appendix S-B. This new baseline discussion acknowledges that LAWA has undertaken and completed a significant number of airport modification projects outside of the Master Plan process, since 1996/97. While this is clearly an improvement over LAWA's earlier refusal to acknowledge the existence of those projects in its environmental review document, it does not resolve the basic legal problem.

Specifically, the projects at issue were approved and undertaken without any of the necessary environmental review. As a result, there has been no public acknowledgment, much less mitigation, of the environmental impacts associated with those projects. This is unacceptable under CEQA and NEPA. LAWA and the FAA cannot include in the Master Plan baseline projects recently completed in disregard of NEPA and CEQA. They must instead evaluate, acknowledge and mitigate for the impacts of those projects.

David Kessler
Jim Ritchie
November 4, 2003
Page 9

The Supplement attempts to downplay the seriousness of the above-described baseline problem by characterizing the post-1996/97 projects as minor. *See* Supplement at 3-5 through 3-6 and Appendix S-B at 42. In fact, as illustrated below, these recent changes at LAX have been significant and have resulted in significant environmental impacts.

LAWA acknowledges that seven South Airfield Complex taxiway improvements have been put into operation since 1996/97. *See* Appendix S-B at 42. According to the Supplement, those improvements consist of five new taxiways (A4, C3, WF, WG and T), the widening/repaving of high-speed exit taxiway T and a seventh undisclosed project. Appendix S-B at 42. These taxiway projects improved the operational efficiency and capacity of the Southside Airfield Complex and therefore increased the overall airside capacity of LAX. *See* Exhibit 4.20(B) to September 2001 Comment Letter. This increased capacity resulted in potentially significant environmental impacts in areas such as noise, traffic and air quality. Nothing in the Supplement acknowledges or evaluates those impacts as it should. To the contrary, the Supplement simply concludes, without support, that the projects were “modest.” Appendix S-B at 42. This is not the case. LAWA’s own documents acknowledge that the taxiway WG, WF and T project were very costly and were undertaken in order to increase the efficiency and capacity of the Southern Airfield Complex. *See* Exhibit 4.20(B) to September 2001 Comment Letter.

The Supplement acknowledges that a number of terminal expansion/improvement projects have been completed since 1996/97 and purports to adjust the project baseline to include these projects for CEQA purposes. *See* Supplement Appendix SB at 42-45. For example, LAWA acknowledges that it allowed American Airlines to construct a new remote commuter terminal with 13 new aircraft parking spaces, and that this project freed up a key position in Terminal 4. *Id.* at 45. LAWA approved this capacity-enhancing project without the necessary environmental review. *See* our September 2001 Comment Letter at 38-39. The 2001 Draft EIS/EIR treated this remote commuter terminal project not as part of the baseline, but rather as part of the No Action/No Project Alternative (and not part of any of the build alternatives). This treatment of the remote commuter terminal project and LAWA’s current effort to include that project in the environmental baseline after the fact are both improper under CEQA and NEPA. LAWA and the FAA must instead evaluate, disclose, and mitigate the environmental impacts of this capacity-enhancing project. The other terminal expansion/improvement projects described in the Supplement should also be treated in

David Kessler
Jim Ritchie
November 4, 2003
Page 10

this way.

Figure S9 in Appendix S-B to the Supplement indicates that in 1997, boarding facilities were completed for the remote aircraft gates located near the west end of LAX. This addition of new gates is a significant example of how LAWA has increased the capacity of LAX facilities recently, outside of the Master Plan process and without the necessary environmental review. The Supplement acknowledges this substantial expansion project but does so only in Figure S9 to Appendix S-B. The project is not described anywhere in the text of the Supplement. As such, the Supplement does not indicate how many remote aircraft gates were added, how many are now located near the west end of LAX, or how these gates have impacted the overall capacity of LAX. In light of these deficiencies, the Supplement does not provide information required under CEQA and NEPA and necessary to inform the public and decision-makers. *See* CEQA Guidelines § 15002(a); 40 CFR 1500.1(b) (NEPA Regulations).

Appendix S-B to the Supplement acknowledges that LAWA has recently added 686 new parking spaces in the Central Terminal Area by constructing a new 989-stall parking structure in place of an existing 295-stall surface parking lot. Supplement Appendix S-B at 45. As the documents attached hereto as Attachment 10 demonstrate, this major new \$18 million parking structure (Parking Structure 6) was improperly approved and constructed by LAWA without any environmental review. In the Draft EIR/EIS, the Parking Structure 6 project was treated as an element of the No Action/No Project Alternative, but not part of any of the build alternatives. Supplement Appendix S-B at 45. This contributed to one of the Draft EIR/EIS's pervasive and most serious flaws: overstating the capacity increase and environmental impacts associated with the No Action/No Project Alternative relative to the build alternatives, in violation of CEQA and NEPA. The Supplement's acknowledgment of the Parking Structure 6 project and inclusion of that project in the year 2000 baseline discussion does not correct this fundamental problem in the Draft EIR/EIS's project description, description of the No Action/No Project Alternative, and definition of the build alternatives.¹

¹ In addition to the Parking Structure 6 project and the other examples described above, Appendix S-B provides other examples of recently-completed projects improperly included in the description of the No Action/No Project Alternative, and not the build alternatives. Such examples include cargo facilities (Singapore, Mercury Air Cargo, FedEx and Cargo Building A); major land acquisitions (Manchester Square and Belford

The Supplement's baseline update is also incomplete as it relates to airport facility modifications because it stops at the year 2000. The document claims that the year 2000 is the most recent "normal" year for which complete data is available for airport operations and that subsequent years are "abnormal" due to the events of September 11, 2001. Even assuming that this logic is correct for airport operations because the demand for air travel dropped off after September 11, 2001, the logic does not hold for physical airport facilities. LAWA has continued with airport facility modification and expansion projects since 2000. Those projects are not, however, adequately acknowledged or evaluated in the Supplement. The airport projects completed since 2000 should all be described and acknowledged in the Supplement so that LAWA and the FAA can properly evaluate and mitigate for the environmental impacts of those projects.

2. The Description of Alternative D in the Supplement to the Draft EIS/EIR is Plagued by Serious Flaws.

a. Remote Gates

The Master Plan Addendum and Supplement imply and indicate at various points that under Alternative D, remote aircraft parking and gate positions now existing at the west end of LAX (i.e., the Remote West Pad Gates) would no longer be considered or counted as available for purposes of Alternative D. See Master Plan Addendum at D-6, Table 2.2-3, 2-27, 2-32. This decision not to count those parking and gate positions would be appropriate if and only if those remote gates and aircraft parking positions are to be permanently eliminated under Alternative D. Unfortunately, although the Master Plan description of Alternative D speaks of "replacing" the remote gates, it does not contain any concrete commitment or plan for the removal and elimination of the parking and gate positions. See Master Plan Addendum at 2-28. To the contrary, the Master Plan indicates that those remote gates will remain in use until at least 2013. See Master Plan Addendum at D-6. Moreover, Supplement Figure ES-5, which depicts Alternative D in 2015, continues to show the remote gates at LAX's west end. See Attachment 7, pp. 11-12.

In order to be consistent with the Supplement's capacity assumptions (and

areas); and airfield improvements (southside taxiway projects).

David Kessler
Jim Ritchie
November 4, 2003
Page 12

all of the environmental analyses conducted for Alternative D based on that assumed capacity), LAWA would have to abandon and demolish the remote parking area and gates. To do so, the Master Plan and Supplement should include provisions requiring that abandonment and demolition. The Master Plan and Supplement should also describe and analyze the potential impacts of any intended uses for the land now used for the remote gate area following decommissioning of the remote gates. For example, the remote gate area would apparently be an ideal location for development of the proposed new employee parking structure at LAX's west end, given that it is an already disturbed area. If LAWA were to develop the proposed employee parking structure at the location currently occupied by the remote gates, it could avoid the environmental problems (e.g., wetlands impacts, endangered species impacts) associated with the currently-proposed site for the employee parking structure.

b. Century Cargo Complex

Table 2.5-2 in the Master Plan Addendum, which describes the cargo facilities proposed as part of Alternative D, contains a number of serious problems that must be addressed. Table 2.5-2 lists an existing cargo building in the Century Cargo Complex as having a square footage of zero. Is this an error? What building is this referring to? Table 2.5-2 also includes two blank lines in its listing of existing cargo facilities in the Century Cargo Complex. These blank lines give the impression that information regarding existing facilities has been deleted or inadvertently excluded from the table. Is this case? Table 2.5-2 and Figure 2.5-1 in the LAX Master Plan Addendum show only one (55,000 square-foot) proposed new cargo facility in the Century Cargo Complex as part of Alternative D. Is this proposed building the cargo facility referred to elsewhere in LAWA documents as Cargo Building B?

Table 2.5-2 and Figure 2.5-1 in the LAX Master Plan Addendum show the 153,000 square foot cargo facility in the Century Cargo Complex as an "existing" cargo facility, despite the fact that the building does not appear in the description of facilities existing at the 1996/97 baseline. See 2001 DEIS/EIR at Figure 3-4. The explanation for this is apparently that LAWA built the 153,000 square foot facility (known as Cargo Building A) in the years since 1997. According to the Supplement Appendix S-B (Existing Baseline Comparison Issues - 1996 to 2000), the structure opened in 1999. Appendix S-B at 46. That Appendix also notes that construction of Cargo Building A was "accounted for in the 2001 DEIS/EIR as part of the future No Action/No Project Alternative." This approach is wholly improper. First, because LAWA was in the middle

David Kessler
Jim Ritchie
November 4, 2003
Page 13

of the Master Plan process when it constructed Cargo Building A, it should have included the project in one or more of the build alternatives in the Master Plan, so that it could be considered as part of LAWA's overall scheme to modify the airport. CEQA Guidelines §§ 15003(h), 15378. At the very least, construction of Cargo Building A should have been subjected to environmental review outside of the Master Plan process, which it was not.

Figure 2.5-1 in the LAX Master Plan Addendum is somewhat unclear regarding the status of and plans for several cargo facilities within the Century Cargo Complex. The approximately 80,000 square foot building known as the TWA Building is shown on Figure 2.5-1 using black outlines, but is not colored like the other existing facilities. The 25,000 square foot Air New Zealand Building is similarly shown on Figure 2.5-1 with black outlines and without coloring like the other existing facilities. Does LAWA commit as part of Alternative D to demolish these cargo facilities? If so, when? If not, the buildings should be shown and analyzed as existing facilities in the Master Plan Addendum and Supplement.

Figure 2.5-1 in the LAX Master Plan Addendum indicates that the approximately 57,000 square-foot facility in the Century Cargo Complex known as Air Freight Building 8 is an existing cargo building that will continue to exist under Master Plan Alternative D. LAWA's Capital Improvement Program for fiscal years 2001 to 2003 indicated that Air Freight Building 8 would be demolished. *See Attachment 8 hereto.* This is particularly important because LAWA appears to have previously relied on this demolition (and the associated reduction in cargo facility square footage) as an offset to the construction of new cargo facilities, by arguing that there would be no resulting net increase in cargo capacity. *See Exhibit 3(M) to our September 2001 Comment Letter.* As such, it would be improper for LAWA to retain Air Freight Building 8 under Alternative D or any other alternative.

Figure 2.5-1 in the LAX Master Plan Addendum also shows the approximately 52,000 square-foot building in the Century Cargo Complex known as Air Freight Building 3 (or the American International Building) as an existing structure. LAWA has previously committed to demolish the structure as part of its Century Cargo Complex redevelopment project. *See Exhibit 3(M) to our September 2001 Comment Letter.* Retention under Alternative D would, again, be inconsistent with LAWA's prior commitment. This reversal is particularly inappropriate because LAWA has relied on the demolition to support its argument that the Century Cargo Complex redevelopment

David Kessler
Jim Ritchie
November 4, 2003
Page 14

project involved no net increase in square footage.

Figure 2.5-1 in the LAX Master Plan Addendum shows just one new cargo facility in the Century Cargo Complex under Master Plan Alternative D: a 55,000 square foot structure. This facility would be located on the same site previously slated by LAWA for development as part of the Century Cargo Complex redevelopment project. Under that plan, LAWA was to build a much larger 150,000 square foot cargo building referred to as Cargo Building B. See Exhibit 3(M) to our September 2001 Comment Letter. Does LAWA propose, as part of Master Plan Alternative D, to abandon its prior plans for construction of the larger facility?

As the above comments make clear, LAWA and the FAA have not clearly or adequately explained the relationship between the new preferred Master Plan Alternative D, existing cargo conditions, and various previously proposed cargo projects (e.g., the Century Cargo Complex redevelopment project). In order to provide full and adequate disclosure, LAWA and the FAA must explain the following: (1) What are/were all of the distinct elements of the Century Cargo Complex redevelopment project? (2) Which of the elements of the Century Cargo Complex or development project have already been implemented? (3) what elements of the project are now incorporated into Alternative D? and (4) what elements of the project would be abandoned under Alternative D?

c. Southern Cargo Complex

Fig. 2.5-1 to the Addendum to the Master Plan indicates that under proposed Master Plan Alternative D, a 39,000 square-foot cargo building would be built in the Southern Cargo Complex - West on a site just west of Sepulveda Boulevard. This is inconsistent with another proposal for development of the same site for which LAWA recently released a draft negative declaration entitled "Mercury Air Group FBO Negative Declaration (April 2003)." That Negative Declaration is attached hereto as Attachment 9. It describes the proposed relocation of Mercury Air Group's operations to the Southern Cargo Complex - West site, including the area the Master Plan proposes to develop with a new 39,000 square foot cargo building. The proposed Mercury Air Group development would include demolition of existing buildings on that site (B-4 Hanger and Air Freight Building 12) and construction of a new building. This inconsistency must be explained or eliminated.

Figure 2.6-1 in the Addendum to the Master Plan depicts proposed ancillary facilities under Alternative D and shows a 121,000 square-foot General Aviation facility located along Imperial Highway at the eastern end of the Southern Cargo Complex - West. This General Aviation use proposal is inconsistent with the Mercury Air Group proposal to use the same site for aircraft parking and a potential fuel farm. See Attachment 9 at Figure 4. This inconsistency must be explained or eliminated.

d. LAX Northside Development

As part of Alternative D, LAWA proposes to proceed with development of the so-called LAX Northside Development Project subject to a daily vehicle "trip cap" of 3,152 a.m. and 3,040 p.m. trips. Master Plan Addendum at 2-117. This daily trip cap is significantly lower than the traffic levels projected for the original LAX Northside Development. *Id.* The square footage of development proposed for the LAX Northside under Alternative D is, however, identical to that of the original LAX Northside Development. *Id.* at 2-117 to 2-118. Neither the Supplement nor the Master Plan Addendum adequately explains how a development of the same size can stay within a much reduced trip cap. In fact, that basic assumption is wholly unsupported by evidence and undermines the validity of the environmental impacts analysis (e.g., traffic, air quality). (For further discussion see report of Tom Brohard & Associates, Attachment 2 hereto, pp. 3-4, 9 [noting in addition an apparent error with respect to the direction of the a.m. cap]).

Moreover, the fact that the Supplement includes traffic generation levels in its analysis of the No Action/No Project Alternative that are higher than those included in its analysis of Alternative D underscores the document's bias against the No Action/No Project Alternative. LAWA's decision to assume lower traffic generation numbers for Alternative D is not supported by evidence in the documentation, and improperly makes the impacts of the No Action/No Project Alternative appear more significant by comparison.

3. The Supplement to the Draft EIS/EIR Relies on a Flawed Description and Analysis of the No Project Alternative.

a. LAX Northside Development

The 2003 Master Plan Addendum and the Supplement to the Draft EIS/EIR

David Kessler
Jim Ritchie
November 4, 2003
Page 16

perpetuate a serious problem regarding the so-called LAX Northside Development. As we explained in our 2001 comments on the Draft EIS/EIR, it was improper to assume development of the massive LAX Northside Development as part of the No Action/No Project Alternative, and doing so artificially inflated the apparent intensity of development under the No Action/No Project Alternative. See September 2001 Comment Letter at 32-34. The additional information and analysis provided in the Supplement illustrates that the document suffers from this same flaw as the Draft EIS/EIR. See Supplement at 3-6. The problems associated with inclusion of the LAX Northside Development in the No Action/No Project Alternative are further exacerbated by the fact that the build alternatives analyzed in the DEIS/EIR assume development less intensive than the LAX Northside Development. Alternative D, for example, assumes that the LAX Northside Development would not proceed as originally approved, but would instead proceed at a less intensive level. See Supplement at 3-47 through 3-48 (assuming that development would produce approximately 50% less traffic than under the LAX Northside Development). The clear result is a strong tendency in the EIS/EIR to overstate the impacts of the No Action/No Project Alternative relative to the build alternatives including Alternative D. This is improper under CEQA and NEPA.

The Master Plan Addendum also states that "Alternative D of the LAX Master Plan identifies the LAX Northside Development as the *baseline* for additional development north of the airport." See Addendum at 2-114 (emphasis added). This is inconsistent with the approach of the Supplement. As explained above, the Draft EIS/EIR and the Supplement both treat development of the LAX Northside as part of the No Action/No Project Alternative, not the baseline. The baseline described in the Supplement does not include any development of the LAX Northside because that area is not developed. The fact that the Master Plan Addendum incorrectly refers to LAX Northside Development as part of the baseline betrays a pervasive problem with the environmental review documents: their repeated efforts to downplay the apparent intensity and severity of the proposed build alternatives by inflating and overstating the intensity and impacts of the No Action/No Project Alternative, so that the build alternatives will look less problematic by comparison.

b. Imperial Terminal

Figure ES-1 in the Supplement (depicting the No Action/No Project Alternative, 2015) shows the Imperial Terminal, an existing passenger terminal located along the Imperial Highway, as an existing cargo building. This is incorrect. As the

David Kessler
Jim Ritchie
November 4, 2003
Page 17

April 2003 negative declaration for the Mercury Air Group FBO shows, the Imperial Terminal is a passenger terminal supporting passenger charter flights. *See* Attachment 9 at A-9, Fig. 3.

c. Southern Cargo Complex

Figure ES-1 in the Supplement indicates that LAWA and the FAA are assuming that under the No Action/No Project Alternative, the existing B-4 Hanger and Air Freight Building 12 in the South Cargo Complex - West would be demolished and replaced by substantial new cargo buildings. This assumption is inconsistent with information contained in the Mercury Air Group FBO Negative Declaration (April 2003), attached hereto as Attachment 9. That document indicates that much more modest development is actually proposed for the site of the existing B-4 Hanger and Air Freight Building 12 in the Southern Cargo Complex - West. LAWA and the FAA make the contrary assumption in the Supplement that more intense and substantial development will occur in the South Cargo Complex - West, even if none of the Master Plan alternatives is approved (i.e., in the No Action/No Project Alternative). This assumption is unreasonable and again artificially inflates the apparent intensity of, and environmental impacts associated with, the No Action/No Project Alternative.

Figure ES-1 in the Supplement, which depicts the No Action/No Project Alternative in 2015, is not clear in its representation of cargo facilities. First, the shades of brown chosen for existing terminal buildings, existing cargo buildings and proposed cargo buildings are so similar as to be essentially the same. As a result, it is impossible to discern what category various buildings fall into (i.e., existing terminal buildings, existing cargo buildings or proposed cargo buildings). Moreover, unlike Figures ES-2, 3, 4 and 5, which show the Master Plan build alternatives, ES-1 does not use the abbreviations "EC" and "PC" to label proposed cargo (PC) buildings and existing cargo (EC) buildings. Together, these problems with Figure ES-1 in the Supplement make it inadequate and misleading.

4. LAWA is Improperly Pursuing Development of Southside Airfield Improvements Outside of and Segmented from the Master Plan Process and Draft EIS/EIR.

According to the Supplement, a central component of Alternative D would be the modification of the southern runway complex (Runways 25L-8R and 25R-8L) to

David Kessler
Jim Ritchie
November 4, 2003
Page 18

address the problem of runway incursions. Supplement at ES-17; Draft Master Plan Addendum at 2-10 to 2-11. These modifications would include relocation of Runway 25L-8R to the south and construction of a new center taxiway between Runways 25L-8R and 25R-8L. *Id.* The documents attached hereto as Attachment 11 demonstrate that LAWA is already committed to undertaking these modifications outside of and separate from the Master Plan. LAWA's July 2003 Quarterly Project Status Report notes, for example, that LAWA has already commenced detailed design work for the project and expects to complete that design work in January 2004. LAWA then proposes to commence construction, which is scheduled to be complete in December 2005.

This significant and irrevocable commitment of resources to the southern runway complex modifications demonstrates that LAWA has already decided to pursue that project regardless of the outcome of the Master Plan process. This constitutes an improper precommitment and/or improper segmentation of the southern runway complex modifications from the rest of the Master Plan. *See* CEQA Guidelines § 15004(b)(2) (prohibiting taking actions that commit agency to course of action, foreclose alternatives or mitigation measures prior to completion of environmental review); CEQA Guidelines § 15378(a) (definition of "Project" includes the "whole of an action"); 40 C.F.R. 1501.2 (NEPA Regulations). Moreover, as illustrated by the analysis in Attachment 7 hereto, the Supplement does not provide the necessary information and analysis of the design options and environmental impacts of the southern runway complex proposal. LAWA and the FAA could not legally approve that project based on the Supplement.

5. The Analysis in the Draft EIS/EIR Improperly Ceases at 2015.

The Draft EIS/EIR is also fundamentally flawed because it fails to look far enough into the future and therefore fails to acknowledge significant and foreseeable environmental impacts. The analysis in the Draft EIS/EIR abruptly stops in the year 2015. No information, analysis or mitigation is provided for impacts occurring in years beyond 2015. This is improper because it is reasonably foreseeable that the proposed Master Plan would have specific environmental impacts in years after 2015 (i.e., more than twelve (12) years in the future). *See* CEQA Guidelines § 15064(d) (requiring consideration of all project-related impacts that are "reasonably foreseeable"). The EIS/EIR fails to take these impacts into account.

This problem has arisen in part because of the delay since LAWA and the FAA released the Draft EIS/EIR. In an apparent recognition of this delay, the

Supplement drops all year 2005 analysis provided in the Draft EIS/EIR. It nonetheless retains 2015 as the horizon for analysis. Instead, LAWA and FAA should have shifted the entire analysis out into the future, looking at at least two study years that are approximately ten years apart to better illustrate the impacts of the project during and after construction (e.g., 2015 and 2025). The short-sighted nature of the analysis is particularly obvious when one considers that the 2001 Southern California Association of Governments ("SCAG") Regional Transportation Plan ("RTP") has a horizon year of 2025, ten years beyond that considered in the Supplement. *See* Supplement at 4-86.

B. The Impacts Analysis in Chapter 4 of the Supplement Is Inadequate in Numerous Respects.

1. Noise

The noise generated by the operations at LAX greatly affect the residents of El Segundo. Parts of El Segundo lie within the 70 dB CNEL, and even the 75 dB CNEL, noise contours around LAX. Supplement, Fig. S4.1-2. Although the Supplement contains new information regarding all Master Plan alternatives in response to prior comments, the noise analysis remains insufficient to disclose the extent of the impacts on El Segundo residents and to formulate adequate mitigation measures. Attachment 1 to this letter, a detailed technical report by Aviation Systems, Inc., describes numerous errors, discrepancies, and flaws in the Supplement's noise analysis. Among those of greatest concern are the following:

- We previously commented that the use of 1996 noise levels as a baseline was improper because noise levels have dropped somewhat since 1996 as a result of newer and quieter aircraft. The Supplement provides information about noise levels in 2000 that confirms that average noise contours in El Segundo were smaller in 2000 than 1996. *See e.g.*, Supplement p. 4-16 ["in the areas north and south of the airport, which are more influenced by takeoff noise than approach noise, the contours are substantially reduced from 1996 baseline conditions . . ."]; graphically portrayed in Figure 4.1-2. Yet the Supplement continues to use 1996 as the baseline year. This results in understating the significance of noise impacts in El Segundo, because the worsening of noise levels in 2015 is being compared to a baseline that is worse than the currently existing conditions. This is exacerbated by the further reduction in noise, due to reduced operations, in later 2001 and 2002. The Supplement uses average noise levels and reports the combined totals

(within the entire airport noise impact area) of the numbers of homes and other properties “newly exposed” to significant adverse noise impacts. *E.g.*, Tables S4.1-25, S4.1-26. The use of these gross numbers in combination with the outdated baseline, which showed noise levels in El Segundo worse than the 2000 levels, results in understating the future adverse noise impacts of the planned airport operations on El Segundo. As such this approach is deceptive and a violation of CEQA’s and NEPA’s requirement that impacts be fully disclosed.

- In response to previous comments, the Supplement provides some information addressing the noise impacts of “single events.” However, the information in the Supplement fails to satisfy the requirements of *Berkeley Keep Jets Over the Bay Committee v. Board of Port Commissioners*, 91 Cal.App.4th 1344 (2001). The Court of Appeal in that case stressed the need to provide information in a form that is useful to residents surrounding an airport in helping to evaluate the impact of future increased air traffic on their daily lives, in particular the interference with sleep and conversation, by individual “single events” of aircraft takeoffs and landings. *Id.* at 1372-83. “Single event” noise is defined as the noise associated with one and only one event. The methodology of the Supplement, however, continues to use only an averaging technique, rather than disclosing individual “single events.” The Supplement should have provided noise contours for each individual takeoff and landing, giving residents important information about the noise impact, frequency, and timing of those “single events,” enabling them to evaluate the significance of those impacts on sleep, conversation, and quality of life. *See e.g.* September 2003 Draft Supplemental Environmental Impact Report, SCH No. 1994113039, for Oakland International Airport ADP, pp. 3.3-28 to 3.3-37, discussing and mapping noise footprints for individual aircraft types and flight paths. The Oakland SEIR, prepared in response to court judgment, is available at www.oaklandairport.com/seir. Such information would also enable LAWA to evaluate appropriate mitigation measures, such as noise abatement departure procedures like those in place today at John Wayne Airport. Instead, the Supplement subsumes all the single events into an “average” contour (the so-called 94 dB SEL contour). This meaningless device perpetuates the time-averaged noise impact methodology used earlier in the Draft EIS/EIR. The environmental analysis for this project should include single event noise contours for each aircraft type on each flight track and their frequency and times of occurrence. Without such information, the analysis remains insufficient and the level of disclosure of impacts does not satisfy legal requirements.

- LAWA formulates a significance threshold of 10 percent of residents being awakened from sleep once every 10 days. There is no documentation justifying the selection of either 10 percent or 10 days. Very loud noise events below this threshold, while treated by LAWA as insignificant, may nonetheless be highly significant to residents awakened from sleep. For this and other reasons use of this threshold results in failure to disclose significant impacts. The Draft SEIR for Oakland Airport's ADP recognized that the significance of sleep disturbance varied among individuals and noise events, and considered, reported and analyzed noise events at 90, 85, and 80 SEL.
- The Supplement, like the Draft EIS/EIR, completely fails to address the impacts of airport noise on speech interference, which is one of the most noticeable aspects of extremely loud aircraft takeoffs and landings. *See Berkeley Keep Jets Over the Bay*, 91 Cal.App.4th at 1375-76.
- The Supplement fails to take into account the noise standards set forth in El Segundo's noise ordinance. Under the CEQA Guidelines, Appendix G, Section XI, a project proponent should consider whether a proposed project would generate noise, or expose persons to noise, in excess of local standards set forth in general plans and ordinances. El Segundo's general noise standards are set forth in its Noise Ordinance, section 7-2-4. For residential property, a noise exceeding five (5) dBA above the ambient noise level is prohibited; for commercial property, noise exceeding eight (8) dBA above ambient noise levels is prohibited. This standard is ignored by the Master Plan analysis. In addition, the single event noise data on which the ordinance is based is, as explained above, not made available in the Supplement. This is a further indication that the data that would be most helpful to residents most affected by airport noise (regarding individual takeoffs and landings) has still not been provided to them.
- The Supplement fails to provide an adequate analysis of the noise impacts on El Segundo of the proposed reconfiguration of the southern runway complex including shifting Runway 25L about 50 feet farther south towards the residences of El Segundo. This is important because El Segundo has urged a serious consideration of the alternative design of an "end-around" taxiway rather than the centerline taxiway that is proposed. Details of the proposed plan must be clarified for adequate analysis. In order to evaluate the comparative noise impacts, a single

event noise analysis of individual takeoffs and landings under each design must be done. In addition, the Supplement fails to provide enough information to develop adequate mitigation measures to lessen the significant adverse noise impacts of this aspect of the plan. *See Attachment 7.*

- There are numerical discrepancies between the different tables used in the Master Plan and Supplement to list the assumed fleet mix. The fleet mix used for noise analysis must be clarified. The discrepancies in assumptions may result in understating noise impacts. *See Attachment 7, p.10.*
- Because, as detailed elsewhere in these comments, the Supplement incorrectly analyzes the capacity of Alternative D, it consequently also fails to disclose the full noise impacts of implementation of that plan. The greater number of passengers that could actually be served by the airport under Alternative D translates directly into increased traffic, leading to increased noise.

2. Land Use

The Supplement's analysis of land use impacts repeats many of the same problems we identified in our comments on the Draft EIS/EIR. As such, the comments presented in our September 2001 letter remain salient and apply to the Supplement's analysis of Alternative D. In addition, we note that the Supplement's land use analysis is largely based on the conclusions reached in the noise impacts analysis section. *See, e.g., Supplement at 4-85.* A complete analysis and critique of the Supplement's noise impacts analysis section is presented in the preceding section of this letter and Attachment 1, and will not be repeated here. We note, however, that the significant issues identified with regard to noise impacts undermine the Supplement's analysis of land use impacts.

Additionally, we have identified the following problems and issues raised by the Supplement's analysis of land use impacts.

- The Supplement properly acknowledges that Alternative C would be inconsistent with the 2001 SCAG RTP, which provides for no expansion at LAX. *See Supplement Technical Report S-1 at 68; Supplement at 4-151.* The same would be true for Alternative D if it is not modified to reduce its capacity, which, as designed, exceeds 78 MAP. The Supplement fails to acknowledge, however, that this inconsistency translates into a potentially significant environmental impact.

Some of the physical manifestations of this impact would include greater noise, traffic, and air quality impacts. The Supplement should acknowledge the fact that Alternative D, as well as C, conflicts with the RTP, and that RTP inconsistency constitutes a significant impact. It should propose mitigation and/or alternatives to address that impact.

- The Supplement correctly acknowledges that development of the Intermodal Transportation Center (“ITC”) on the vacant land previously slated for development as Continental City would preclude development of that land as provided in the Los Angeles General Plan. Supplement at 4-195 to 4-196. Specifically, the Continental City site is designated as a “Regional Center” development site in the Los Angeles General Plan Framework Element (excerpt attached hereto as Attachment 12). Regional centers are intended to contain a diversity of uses (office, retail, health facilities, entertainment, etc.) and to “serve as a focal point of regional commerce, identity and activity.” Attachment 12. The Supplement concludes that the proposal to develop the Continental City site as an ITC rather than a regional center is not significantly inconsistent with the General Plan and would not require a general plan amendment. As support for this conclusion, the Supplement points to two aspects of the proposed ITC: (1) its focus on multi-modal transportation and (2) its promotion of day and night activities on the site. While it is certainly true that these are secondary characteristics of a regional center, they are not the sole, most important or defining characteristics. *See* Attachment 12. As such, they do not, in and of themselves, render the ITC (an aviation serving use) consistent with the “Regional Center” general plan designation. The Supplement should therefore acknowledge that the ITC is inconsistent with the general plan.
- The Supplement deletes from consideration those land use/noise mitigation measures now being evaluated as part of the Community Noise Roundtable Program (14 C.F.R. Part 150 and 161 flight procedures). Supplement at 4-198. The deletion is improper. LAWA and the FAA have a legal obligation to include those potentially feasible mitigation measures in the EIS/EIR for the Master Plan.
- The Supplement includes mitigation measures that would require LAWA to conduct research regarding the impact of aircraft noise at various levels on learning by schoolchildren. Supplement at 4-210 (MM-LU-3). Another mitigation measure would require LAWA to provide sound insulation to schools found to

exceed a threshold of significance developed based on the results of that study. Supplement at 4-210 (MM-LU-4). These mitigation measures lack legally required specificity and enforceability. It is not clear, for example, what kinds of "industry experts" would, under the mitigation measures, be called on to conduct a "peer review" of and "accept" the study results. Would those experts be specialists in learning or aviation noise? How would the experts be selected? What would the time frame be for completion of the study? Would elements of the Master Plan be stayed pending results of the study? It is also unclear what LAWA would be obligated to do regarding noise in schools if the experts conducting the peer review of the study cannot agree regarding what the threshold of significance should be. The mitigation measures should be revised to answer the above questions and include a mechanism for resolving such potential disagreement among experts. That mechanism should be conservative and err on the side of caution and reducing noise impacts in the affected schools.

- The Supplement indicates that the 1988 ANMP is "currently" being updated and "is scheduled for completion in the second quarter of 2003." Supplement at 4-87. Given that the second quarter of 2003 has now passed, this information appears to be out of date. The Supplement should have provided more complete information regarding the 2003 ANMP and should have analyzed the extent to which the ANMP comports with the requirements outlined in the mitigation measures described in the Supplement.

3. Surface Transportation

The Supplement fails to disclose the severity of the impacts of the Master Plan alternatives, and Alternative D in particular, on increased traffic, as well as the noise and air pollution generated by that traffic. The traffic analysis contains numerous analytical errors, omissions and flawed assumptions, which are documented in detail in Attachment 2 to this letter. Among those problems are the following:

- The Supplement continues the use of 1996 traffic data as the baseline for purposes of evaluating the severity of traffic impacts, and fails to respond to numerous previous comments pointing out flaws in the baseline calculations. The Supplement fails to adequately document why the use of 7-year-old traffic data as the environmental baseline suffices under CEQA and NEPA.

- The Supplement substantially understates the traffic impacts of Alternative D due to its reliance on the artificially low figure of 78.9 million annual passengers (MAP), which is based on unrealistic and unsupportable assumptions and is, based on our independent analysis, substantially lower than the actual gate capacity of Alternative D. Each additional passenger served translates to an increase in the number of airport-related trips and the resultant environmental impacts.
- There are substantial numerical errors and inconsistencies in the Supplement. For example, the traffic analysis uses 5,953 daily construction employee trips (Supplement Table 4.3.2-9), while based on the 5,992 total construction personnel disclosed in Chapter 4.20 of the Supplement, more than twice that number of trips (11, 273) would be generated.
- The analysis of construction traffic fails to take into account the impacts of construction trips during many high volume traffic hours during the day, limiting its discussion to a single peak morning and afternoon hour and therefore failing to disclose significant impacts during other times. Many other impacts of construction activity are similarly not disclosed and therefore inadequately mitigated.
- The analysis of freeway impacts fails to take into account the existing levels of congestion on the I-105 and I-405 freeway mainlines. The Supplement fails to analyze numerous constricted and congested segments on these freeways. The ramp improvements recommended as mitigation will fail to improve the freeway congestion caused by this project unless capacity is increased on the segments of the freeway that are already operating at or above capacity. The Supplement's failure to acknowledge this results in its erroneous conclusion that freeway impacts are less than significant.
- Errors in the analysis of intersections located in El Segundo (including, for example, incorrect assumptions regarding existing turn lanes, omission of a driveway into LAX, incorrect signal phasing, and arbitrary volume adjustments) result in an inaccurate disclosure of traffic impacts and inadequate discussion of mitigation measures for many of those intersections.
- The Supplement does not provide an adequate analysis of the phasing of construction of the improvements contemplated in Alternative D and the

mitigation measures proposed, so that in several cases it appears that mitigation measures will not be in place until years after the components of Alternative D that make the mitigation necessary. In addition, no traffic analysis was provided for 2005, making it doubly difficult to understand the impacts during interim years and to coordinate mitigation. This results in further failures to disclose the extent of the impacts during buildout of the project.

- The Supplement fails to remedy problems previously identified regarding calculations of future cumulative traffic conditions. It also fails to use current lists of pending local projects in its analysis of cumulative traffic impacts, apparently relying on the now outdated list that was utilized in the 2001 Draft EIS/EIR. As a result, the analysis of cumulative traffic impacts is not accurate and may omit significant effects.

4. Social Impacts

a. The Supplement's Analysis of Employment and Socio-Economics Perpetuates the Same Flaws and Misconceptions as the Draft EIS/EIR.

The Supplement, like the Draft EIS/EIR, continues to imply that the economic growth of the Los Angeles region under the No Action/No Project Alternative would fall far short of the growth projected under Alternatives A, B, or C due to the fact that growth would be constrained at LAX itself under the No Action/No Project Alternative. Additionally, the Supplement now draws the same conclusion with regard to Alternative D, based on the assumption that Alternative D would limit growth at LAX to nearly the same extent as the No Action/No Project Alternative. As discussed in our prior comments, (September 2001 Comment Letter at 67-68), this conclusion is not sound because it fails to consider the regional growth that would be generated at other airports due to the growth constraints placed on LAX. The environmental analysis presented considers only the jobs and economic growth directly generated by LAX itself, rather than taking a region-wide approach that would consider jobs and other economic benefits generated at other regional airports under the regional airport approach. *See CEQA Guidelines § 15064(d)* (requiring that all reasonably foreseeable impacts receive consideration).

Moreover, the analysis of Alternative D, as well as the analysis of the other

David Kessler
Jim Ritchie
November 4, 2003
Page 27

alternatives, does not take into account the post-September 11, 2001 security requirements at airports, which have added and will continue to add a substantial number of jobs in law enforcement and security at LAX and other airports. Supplement at 4-298, fn. 71. See Attachment 13 (news reports of substantial recent and proposed increases in security personnel at LAX). This, combined with the failure to consider regional growth due to constraints placed on LAX growth, indicates that the Supplement, like the Draft EIS/EIR, underestimates the growth that will occur under both the No Action/No Project Alternative and Alternative D, and renders the inter-alternatives analysis inaccurate.

b. The Supplement's Analysis of Relocation of Residences and Businesses Is Inadequate.

Although the Supplement's discussion of impacts due to the relocation of residences and businesses purports to consider demographic and economic changes that have occurred in the LAX region since the 1996 baseline year, its consideration of those changes is dismissive at best. The Supplement states that "in general, the differences between the 1990 and 2000 U.S. Census data do not reflect substantial demographic changes that would alter the analysis presented in the Draft EIS/EIR." Supplement at 4-303.

However, Table S2 of Appendix S-D reveals that not only has the minority population within the study area as a whole increased from 78% to 84% between 1990 and 2000, but the percentage of the population within the study area living below the poverty level has also increased from 18% to 23% in those ten years. Supplement Appendix S-D at 5. Under Alternative D, residential acquisition would generally occur in the Manchester Square area. In that census tract, CT 2774, the minority population was 90.29% of the total population in year 2000, with 27.11% of the total population living below the poverty level. Supplement at Appendix S-D, Table S3. Meanwhile, the Los Angeles Times recently reported that the median price for a home in Los Angeles County rose 23.3% between July 2002 and July 2003 from \$266,000 to \$328,000. "Home Sales Stay on Fire, Especially in Inland Empire" by Bonnie Harris, *Los Angeles Times*, August 21, 2003, attached as Attachment 14.

Although the acquisition of residential properties within the Manchester Square neighborhood is an ongoing program, under Alternative D, the City of Los Angeles would accelerate this acquisition once the Master Plan has been approved in order to comply with the Master Plan's Construction Sequencing Plan. Supplement at 4-

David Kessler
Jim Ritchie
November 4, 2003
Page 28

304. Accordingly, a largely minority population, nearly a third of whom are impoverished, would be forced into one of Los Angeles County's worst housing markets in decades. Although the Master Plan purports to address this potential affordable housing crisis through Master Plan Commitment RBR-1, this "commitment" merely defers mitigation. *Id.* at 4-305. Commitment RBR-1 states that LAWA will prepare a Residential and Business Relocation Plan and expand its current relocation program at some unspecified point in the future. *Id.* Given that the City of Los Angeles is supposed to move forward with acquisition and/or condemnation of the Manchester Square neighborhood as soon as the Master Plan is approved (Supplement at 4-304), it is obvious that the "Residential and Business Relocation Plan" should have been prepared as a part of this Draft EIR/EIS and absolutely must be prepared prior to the approval of the Master Plan. Deferral of this important mitigation defeats the purpose of the CEQA planning process which requires that all impacts and options for mitigation be evaluated prior to project approval. *See* CEQA Guidelines §§ 15002(a)(3), 15004(a), 15003(h).

Finally, although the Supplement attempts to address the acknowledged shortfall in real estate suitable for light industrial uses, the attempt relies upon too many vague and uncertain conditions. The Supplement identifies relocation impacts to light industrial uses as significant. *Id.* at 4-314. Through Mitigation Measure MM-RBR-2, the Supplement attempts to address these impacts by stating that LAWA will coordinate with the City of Inglewood and the County of Los Angeles to identify residential properties that could be acquired and converted for light industrial uses. *Id.* at 4-312. Not only has no such program yet been developed—thus continuing the EIS/EIR's trend of deferred mitigation—but such a program would rely on: (1) the existence of suitable residential properties; (2) the financial and practical ability to acquire them; (3) the ability to relocate residents, many of whom are low-income; (4) approval from the local jurisdictions to rezone residential properties for light industrial uses; and (5) the financial ability to construct light industrial facilities. None of these contingencies are provided for in the documents; they are not even discussed in detail. Such vague and uncertain mitigation does not support the Supplement's conclusion that project-level and cumulative relocation impacts would be less than significant with mitigation.

c. The Supplement's Analysis of Environmental Justice Is Inadequate and Continues to Rely On Much of the Same Flawed Reasoning and Meager Factual Support As the Draft EIS/EIR.

Comments we presented in our September 2001 Comment Letter on the Draft EIS/EIR regarding environmental justice remain in force with regard to this Supplement. For example, there continues to be a lack on information regarding certain health risks associated with living so close to a major airport, especially concerning chronic respiratory illnesses such as asthma, which are more prevalent among populations disproportionately affected by LAX, such as minority and low-income communities. Additionally, this section of the Supplement relies too heavily on the purported "benefits" that will be provided by the Master Plan, without offering any commitments or mitigation measures to make those benefits an enforceable reality. Supplement at 4-339 to 4-341.

Moreover, although the Supplement acknowledges that Alternative D will expose three schools that are located within minority and/or low-income communities to greatly increased noise, (Supplement at 4-324), rather than providing mitigation to directly address that identified impact, the Supplement merely proposes to "study" whether such exposure is a bad thing. *Id.* at 4-338 (MM-LU-3). Studies regarding the impact of noise on learning already exist, and indeed the Supplement states that LAWA has evaluated recent research literature. Supplement at 4-11. *See, in addition, "A Prospective Study of Some Effects of Aircraft Noise on Cognitive Performance in Schoolchildren," Psychological Science, September 2002 (Vol. 13, No. 5), by Staffan Hygge, Gary W. Evans, and Monika Bullinger, attached as Attachment 15; see also Exhibits 4.1(A) and 4.1(B) to our September 2001 Comment Letter.* There is no reason for LAWA to defer mitigation and reinvent the wheel by conducting its own studies when the information on impacts of severe noise on the learning of school children already exists. Instead, LAWA should commit to providing actual mitigation—at a minimum, sound insulation—to the impacted schools without delay. Without adequate mitigation to address this identified significant impact, the EIS/EIR cannot lawfully be approved. CEQA Guidelines § 15091(a)(1).

5. Induced Socio-Economic (a.k.a. Growth-Inducing) Impacts.

The Supplement's analysis of induced socio-economic (growth-inducing) impacts continues the inaccurate logic of the Draft EIS/EIR: despite the fact that

David Kessler
Jim Ritchie
November 4, 2003
Page 30

Alternative D will involve massive construction and provide numerous economic benefits to the LAX region, it will not induce any growth. Instead, according to the Supplement, Alternative D will actually lead to a decrease in jobs and population due to "productivity increases" in the manufacturing sector. For the reasons set forth in our September 2001 Comment Letter, we reject to this conclusion. See September 2001 Comment Letter at 74-5.

Additionally, although the Supplement notes that through property acquisition, Alternative D will "deplete the total supply of industrial space in the LAX vicinity by approximately 17 acres . . ." and that there is currently only 500,000 square feet of vacant industrial space in the vicinity, the Supplement nevertheless concludes that this will not be a significant growth-inducing impact. Supplement at 4-353 to 4-354. The Supplement bases this conclusion on reasoning that is not only faulty, but defies established legal principles of environmental review. To wit: because the shortfall in available industrial space will likely lead other jurisdictions to rezone land for industrial uses and because those rezones will trigger discretionary approval, and thus environmental review, by the local jurisdictions, there is no significant impact here. Supplement at 4-354 ("To the extent that induced demand in other jurisdictions would exceed available supply within industrially designated and zoned land, proposed industrial development in those instances would be subject to discretionary approval by these jurisdictions and, therefore, would require environmental review. The potential for project-induced demand for industrial development to result in impacts is, therefore, considered to be less than significant.").

This is not how CEQA and NEPA work. If this Project will trigger growth, whether directly or indirectly, then the impacts of that growth must be analyzed now, not at some later date in some later environmental review. See e.g., Pub. Res. Code § 21100(b)(5); *City of Antioch v. City Council of Pittsburg*, 187 Cal.App.3d 1325, 1337 (1986). It does not matter, for the purposes of the environmental review for the Master Plan, whether the specific future projects induced by this Project will be subject to later environmental review; the impacts of such growth inducement must be identified and analyzed here. CEQA mandates that environmental impacts be identified and analyzed in the EIR, not at a later date. See *Sundstrom v. County of Mendocino*, 202 Cal.App.3d 296, 307 (1988) (holding a negative declaration invalid where a county approved a project while postponing the resolution of uncertainties regarding environmental impacts to a later date).

David Kessler
Jim Ritchie
November 4, 2003
Page 31

Furthermore, although the Supplement states that "Alternative D could result in greater intensification of existing industrial properties in the area or a greater potential for the conversion or recycling of other land uses," (Supplement at 4-354) this is not identified as a significant impact and no further analysis is provided. This conclusion is simply left hanging. This lack of follow-through is not acceptable for the purposes of environmental review. For all of these reasons, the Supplement's analysis of induced socio-economic impacts is as inadequate and flawed as the Draft EIS/EIR's.

6. Air Quality

The Supplement provides some new analysis of air quality impacts, apparently in response to prior comments. However, it still fails to address many of the inadequacies identified in prior comments, fails to include adequate mitigation measures, and fails to disclose the severity of the air emissions impacts of the construction and operations of the Master Plan alternatives. The air quality analysis contains numerous analytical errors, omissions, inconsistencies, and flawed assumptions. These are documented in detail in the technical comments prepared by Dr. J. Phyllis Fox and Petra Pless, included as Attachment 3 to this letter. As these reports indicate:

- The Supplement fails altogether to analyze PM 2.5 emissions, the major component of particulate emissions from airport operations, despite currently applicable CARB standards.
- The Supplement utilizes an outdated PM 10 standard, rather than the currently applicable and more stringent CARB standard; this results in understatement of significant impacts.
- The Supplement substantially understates background ambient concentrations of air pollutants by deviating from regulatory guidelines and standard practice, resulting in failure to disclose violations of ambient air quality standards.
- Without providing any explanation in the text, the Supplement provides a completely new analysis of the air quality impacts of construction activities for the airport improvements under consideration. The new construction emissions calculations result in substantially lower conclusions regarding emissions. They are not adequately supported in the documents, and appear to utilize invalid methodology and numerous incorrect assumptions which result in understating the

construction impacts.

- The Supplement utilizes an updated model (EDMS 4.11) to develop projected air pollutant emissions for the baseline and all Master Plan alternatives. It fails to use a consistent approach however. Instead, it calculates the emissions for Alternative D using the updated model but then, rather than calculating emissions for all alternatives under the new model, uses a ratio to “adjust” the emissions projections for other alternatives. This approach is scientifically flawed and makes comparisons between the emissions of the alternatives meaningless.
- The Supplement fails to provide a meaningful analysis of total air emissions impacts. Instead, it improperly piecemeals the analysis by reporting separately the on-airport, construction, and off-airport impacts.
- The Supplement uses unrealistic and unsupported projections regarding the effectiveness of mitigation measures, resulting in further understatement of impacts.
- The proposed air quality mitigation measures are inadequate because the proposed measures are of dubious value in reducing air emissions, many are impermissibly vague and not adequately enforceable, numerous feasible mitigation measures are omitted and the measures provided are not enforceable. Please see the lists of proposed mitigation measures (which have been adopted elsewhere) provided in Attachment 3. Particularly given the nonattainment status of the South Coast Air Basin with regard to ozone, CO and PM10, LAWA must act more aggressively in utilizing effective and enforceable air quality mitigation measures.
- The Supplement, like the Draft EIS/EIR before it, fails to provide sufficient data for the technical consultants to check the calculations. We have submitted formal records requests for the necessary data (Attachment 16), and have been assured that the information will be provided, but have not received the materials in time to utilize them for these comments. As soon as possible after receiving the requested documents, we will submit supplemental comments on the Supplement analysis, as appropriate.
- The Supplement also gives short shrift to analysis of public health impacts, in substantial disregard of the comments we submitted in 2001. The evaluation of

David Kessler
Jim Ritchie
November 4, 2003
Page 33

human health risks caused by toxic air pollutant emissions associated with LAX operations under the various alternatives, including Alternative D, uses outdated databases and underestimates emissions from various airport sources. The Supplement continues to use an inappropriate threshold of significance for both chronic noncancer health risks, and cancer risks. And it makes no attempt to formulate effective mitigation measures for human health impacts. These analytical deficiencies and others are detailed in Attachment 5 to this letter, at pp. 34-40.

7. Hydrology and Water Quality

Our comments regarding the Supplement's hydrology and water quality analysis were prepared by Phyllis Fox, Ph.D. and Petra Pless, D.Env. Those comments are attached hereto as Attachment 5. Resumes for these experts are provided as Attachment 4.

The comments prepared by our experts indicate that the EIS/EIR's treatment of water quality impacts remains inadequate and inaccurate. The Supplement raises new issues and does not adequately address the serious problems previously identified in our comments on the Draft EIS/EIR, including reliance on outdated data and understated pollutant loads. The EIS/EIR excludes numerous important pollutants and fails to provide for mitigation measures that are well developed and specific enough to allow for an objective evaluation of effectiveness, much less enforcement. Accordingly, the Draft EIS/EIR underestimates impacts to water quality and sets forth insufficient mitigation measures.

8. Section 4(f) Resources

As discussed in our September 18, 2003 Letter (page 77), section 4(f) of the Department of Transportation Act of 1966 requires federal agencies to identify and avoid impacts to parklands, recreation areas, historic resources, and wildlife and waterfowl refuges. 49 U.S.C. § 303(c). Under section 4(f), codified at 49 U.S.C. § 303, the Secretary of Transportation may approve a transportation project requiring the "use of publicly owned land of a public park, recreation area, or wildlife and waterfowl refuge of national, State, or local significance, or land of an historic site of national, State, or local significance (as determined by the Federal, State, or local officials having jurisdiction over the park, area, refuge, or site)" *only if* no "prudent and feasible" alternative to using

David Kessler
Jim Ritchie
November 4, 2003
Page 34

the resource exists, and the project includes “all possible” planning to minimize harm to the resource resulting from the use. *Id.* Like the Draft EIS/EIR before it, the Supplement has not only failed to fully examine the section 4(f) resources impacted by the Master Plan Alternatives, including Alternative D, but it has also failed to fully develop alternatives to the use of these resources and to provide “all possible” mitigation measures to minimize harm.

First, the Supplement fails to identify all the section 4(f) resources that may be impacted by the Master Plan Alternatives, including Alternative D. *See also* September 2001 Comment Letter at 77. Specifically, although resources subject to section 4(f)’s protection specifically include historic resources of national, *State, or local* significance, (*see* 49 U.S.C. § 303(c); Supplement, Appendix S-F at 1), both the main text of the Supplement and Appendix S-F to the Supplement fail to consider impacts to historic resources of State and local significance. For example, the Intermediate Terminal Complex, the International Airport Industrial District and the Morningside Park Neighborhood are not included in the documents’ list of section 4(f) resources, despite the FAA’s own determination that these resources are eligible for listing as State and/or local historic resources. *See* Supplement at 4-436, Table S4.9.1-1.

Regardless of whether these resources are ultimately determined to be eligible for listing on the federal National Register of Historic Places—a process which is still ongoing—the mere fact that these resources are eligible for State and/or local listing triggers section 4(f). The omission of any discussion of these resources under section 4(f) must be corrected for this document to comply with federal law. Under Alternative D, at least one of these section 4(f) resources--the International Airport Industrial District--will be partially demolished, destroying the entire district’s integrity. Supplement at 4-437. Without full consideration of these identified section 4(f) resources, including exploration of all “prudent and feasible” alternatives to their use and “all possible” planning to minimize harm to these resources, this project simply can not comply with section 4(f).

Second, as discussed in the Supplement and Appendix S-F, the FAA’s determinations of eligibility for both the National Register of Historic Places and the California Register, are subject to consultation and concurrence by the California State Historic Preservation Officer (“SHPO”). *See* 36 CFR § 800.2(c)(1); Supplement, Appendix S-G at 1. This consultation is currently ongoing and thus, not only has the SHPO not yet concurred with the FAA’s determinations regarding the above discussed

resources, the SHPO has also not concurred with the FAA's determinations regarding the ineligibility of the 1961 Air Traffic Control Tower for federal, State, or local listing. Even if this resource is ultimately determined to be ineligible for listing in the National Register of Historic Places, it may still be eligible for State or local listing, either of which would trigger the protections of section 4(f). Without consideration of impacts to this potentially significant historic resource, the Draft EIS/EIR is incomplete.

Third, even where the Supplement correctly identifies certain section 4(f) resources, it fails to fully consider and mitigate impacts to those resources. For example, although the document identifies Vista del Mar Park as a section 4(f) resource, it finds that a 3.3 dB CNEL increase from Year 2000 conditions under Alternative D will not constitute a constructive use of the park. Supplement at 4-427. Through flawed reasoning, the Supplement determines that because the noise level at the park was at one time almost as bad as it will be under Alternative D, normal use of the park will not be disrupted by bringing the noise level back up again. *Id.* The document ignores the relevant fact that noise levels at the park have been much lower recently than they would be under Alternative D. Specifically, the Supplement concludes that, although the park had a noise level of 75.7 dB CNEL in Year 2000, no constructive use will occur under Alternative D's 79.1 dB CNEL, because once upon a time in 1996, the park had a 79 dB CNEL. *Id.* Simply put, the Supplement concludes that the increase in noise will not impact normal use of the park because the park is already noisy and was historically even noisier. *Id.* No support for this conclusion is cited in the Supplement and similarly unsupported conclusions are made with regard to Dockweiler Beach State Park. *Id.* Without further support for these findings, the Supplement is inadequate under section 4(f).

9. Historic Resources, Including Architectural, Archeological, Cultural, and Paleontological Resources

Like the Draft EIS/EIR, the Supplement's identification of Historic/Architectural and Archeological/Cultural Resources and analysis of impacts to those resources is legally inadequate. As discussed in our September 2001 Comment Letter, the Draft EIS/EIR downplayed LAWA's responsibility for the alteration and destruction of certain resources, including CA-LAN-1118 and the 1961 Air Traffic Control Tower; the Supplement suffers from the same flaw. Additionally, a number of other flaws are revealed in the Supplement, including the failure to: identify resources; determine their eligibility for listing on federal, State, or local registers; adequately

David Kessler
Jim Ritchie
November 4, 2003
Page 36

describe and document those resources within the EIS/EIR; and identify alternatives and/or mitigation measures that would avoid or lessen impacts to these resources.

For example, despite the passage of almost two years since the circulation of the Draft EIS/EIR, no final determination has been made regarding many resources' eligibility for the National Register of Historic Places, the California Register of Historical Resources, or local registers. See Supplement, Appendix S-F at 4. Under Section 106 of the National Historic Preservation Act of 1966, 16 U.S.C. § 470 *et seq.*, the federal government must make determinations of eligibility for the National Register of Historic Places in consultation with the State Historic Preservation Officer ("SHPO"). See 36 CFR § 800.2(c)(1). According to the Supplement, the SHPO has yet to concur with the FAA's determinations that the Intermediate Terminal Complex, the International Airport Industrial District and the Morningside Park Neighborhood are not eligible for the National Register of Historic Places. Likewise, as noted above, the SHPO has not yet concurred with the FAA's determination that the 1961 Air Traffic Control Tower is not eligible for federal, State, or local listing due to recent modifications made to the exterior of this historic structure by LAWA.

Without a final determination regarding whether the impacted resources are eligible for listing on the National Register of Historic Places, there can be no compliance with Section 106 of the National Historic Preservation Act of 1966, 16 U.S.C. § 470 *et seq.* Moreover, with regard to the 1961 Air Traffic Control Tower: even if this resource is not eligible for listing on the National Register of Historic Places, eligibility for listing on State or local registers would implicate not only section 4(f), discussed above, but also CEQA. Without such a determination, impacts to this potentially historic structure cannot be fully understood, let alone avoided or mitigated.

Additionally, despite the Supplement's recognition that Alternative D would adversely impact the International Airport Industrial District—determined by the FAA to be eligible for both State and local listing—little information is provided regarding this important resource. Not only would Alternative D demolish eleven buildings contributing to this historic district, it would also “compromise the overall integrity and configuration of the district resulting in a significant impact at the state and local levels.” Supplement at 4-436. Despite the acknowledged direct and cumulative significant impacts resulting from demolition of these historic resources, almost no information is provided in the Supplement or Appendices regarding the International Airport Industrial District and what buildings in particular will be demolished.

David Kessler
Jim Ritchie
November 4, 2003
Page 37

As the Supplement recognizes, Alternative D's partial demolition of the International Airport Industrial District is a significant direct and cumulative impact under CEQA. Supplement at 4-436. The District is a "significant exception[]" to the utilitarian appearance of the majority of the industrial architecture within the Area of Potential Effects ("APE"). Supplement, Appendix S-G at 39. Designed by "national[ly] acclaim[ed]" architect S. Charles Lee, many of the buildings of the District have "distinctive entries with canopies, supports and fenestration derived from both the Streamline and the Modern architectural vocabularies." *Id.* Despite this, only one photograph of the District is provided in the Supplement. *Id.* at Figure S14; *see also id.* at Attachment 2, DPR 523 Form (same photograph). This photograph is taken at a distance from almost a bird's eye view and reveals a view of rooftops and blacktop; the facade of one building can be seen. *Id.* This single photograph of an acknowledged historic district is totally inadequate for the purposes of environmental review. At the very least, individual photographs of the facades of buildings contributing to the District, with particular care given to buildings proposed for demolition, should be included in the EIS/EIR. Without more visual representations of the resources to be impacted and without the identification of the specific buildings to be demolished, this document fails to meet the minimum standards of for environmental review that we have identified under federal and State law.

Like the Draft EIS/EIR, the Supplement fails to provide adequate—or rather *any*—analysis of the feasibility of rehabilitating, remodeling, and reusing historic structures, including the buildings within the International Airport Industrial District. The EIS/EIR must address the option of adaptively reusing the buildings the FAA and LAWA propose for demolition according to the standards established by the Secretary of the Interior and the California Office of Historic Preservation.

Finally, although the Supplement recognizes that a significant impact will occur to the region's paleontological resources due to the grading and excavations involved in Alternative D, as well as the other build alternatives, the document continues to defer important mitigation—in violation of federal and state law—that could potentially mitigate some of the significant impacts to these resources. Specifically, Mitigation Measure MM-PA-1, a mitigation for Alternatives A, B, C, and D, defers development of a monitoring and fossil remains treatment plan for construction-related activities until after Project approval. Supplement at 4-446. Such a plan should have been developed and made available for comment as part of the Draft EIS/EIR. There is no reasonable justification for postponing the development of this plan until after the

David Kessler
Jim Ritchie
November 4, 2003
Page 38

Project is approved, and the document does not attempt to offer any. An acceptable monitoring and fossil remains treatment plan for construction-related activities should be developed and circulated for public comment and should be included in any final version of the EIS/EIR for this Project. Failure to do so constitutes impermissible deferral of mitigation designed to address identified significant direct and cumulative impacts.

10. Biotic Communities

The Supplement's analysis of impacts to biological resources employs the same faulty methodology as the Draft EIS/EIR's analysis of biological impacts, and, thus, its conclusions regarding impacts and mitigation are likewise fundamentally flawed and misleading. Like the Draft EIS/EIR, the Supplement relies on the quantification of "habitat units" to analyze the impacts the Project will have on biological resources. Although the technique has been renamed the "Mitigation Land Evaluation Procedure" ("MLEP") and is no longer called the "Habitat Evaluation Procedure" ("HEP"), the methodology remains the same. As discussed in our September 2001 Comment Letter, the MLEP contradicts accepted methodology for assessing impacts to biological resources, including habitat. By examining factors that are not relevant to the needs of sensitive species and relying on the fiction of the "habitat unit" that is at odds with the reality of sensitive species' habitat needs, the MLEP greatly underestimates the impacts the Project will have due to the destruction of hundreds of acres of existing habitat. See September 2001 Comment Letter at 84.

Because the Supplement relies on the same flawed methodology as the Draft EIS/EIR, our comments provided in our prior comments remain entirely applicable to this Supplement and to the analysis of Alternative D. Additionally, despite the inclusion of new information and new mitigation measures, the Supplement not only subjects itself to the same failures as the Draft EIS/EIR, it compounds these failures by providing new information and mitigation that is misleading and inadequate.

For example, several times in its analysis of impacts to biological resources, the Supplement appears to compare the impacts of Alternative D to the impacts that would result from the other build alternatives, instead of conducting a comparison to baseline conditions or even to the No Action/No Project Alternative. See e.g., Supplement at 4-466 ("Potential impacts to flora and fauna resulting from increased concentrations of air pollutants [under Alternative D] would be the same as other build alternatives."). This kind of comparison is misleading and serves to minimize the

David Kessler
Jim Ritchie
November 4, 2003
Page 39

apparent impacts of each build alternative.

Additionally, although the Supplement identifies numerous significant impacts to biological resources—including loss of state-designated habitat and impacts to Lewis’s evening primrose, sensitive arthropods, the silvery legless lizard, the San Diego horned lizard, the burrowing owl, the western spadefoot toad, the San Diego black-tailed jackrabbit, the loggerhead shrike, and 300 mature trees (*id.* at 4-465 to 466)—the Supplement nevertheless concludes that there will be no significant impacts with mitigation (*id.* at 4-479). The Supplement reaches this result by purporting to require habitat replacement. However, much of this habitat replacement is proposed for land that is already designated and protected habitat—i.e. land within the El Segundo Blue Butterfly Habitat Preserve. *See e.g.*, MM-BC-13, Supplement at 4-478 (“Opportunities for restoration include . . . 36.11 acres from removal and restoration of 50 percent of the existing roadways to Southern Fore-dune . . .”). By relying on the flawed methodology of “habitat units,” the Supplement announces that it is creating new habitat to replace habitat that will be destroyed by the Project by merely improving the “habitat value” of already existing designated habitat. In reality, no new habitat is created; at best, existing protected habitat is merely improved. The result is that impacts to biological resources are grossly underestimated and not truly mitigated.

Another example of the Supplement’s inadequate mitigation of biological impacts is the mitigation it proposes for the removal of over 300 mature trees. Although the Supplement acknowledges that this significant impact will occur as a result of the proposed LAX Northside/Westchester Southside project and that the destruction of these mature trees will have a significant impact on the nesting activities of certain sensitive species, including raptors, the proposed mitigation is thoroughly inadequate. First, the mitigation fails to minimize the significance of the impact involved. The replacement trees will not be mature, and, thus, at a minimum, there will be significant short term impacts until the replacement trees reach maturity (which could take decades). Moreover, the Supplement leaves the determination of the species of replacement trees to the discretion of LAWA. *Id.* at 4-471. As discussed in our previous comment, LAWA has a documented history of using inappropriate, non-native, and invasive landscaping both within and near sensitive habitats. September 2001 Comment Letter at 84-85. Any mitigation for the destruction of these 300 mature trees should require LAWA to plant native species, or, where the use of native species is infeasible, native-compatible species.

A final example of the Supplement’s inadequate attempts to mitigate

David Kessler
Jim Ritchie
November 4, 2003
Page 40

impacts to biological resources is its deferral of the development of relocation and monitoring plans to an entirely undefined later date. Supplement at 4-475 to 4-477 (MM-BC-9). Rather than develop relocation and monitoring programs for inclusion in the Supplement, the Supplement has instead impermissibly deferred development of these important mitigation measures. The formulation of mitigation measures can not be deferred until after project approval; rather, “[m]itigation measures must be fully enforceable through permit conditions, agreements, or legally binding instruments.” 14 CCR § 15126.4 (a)(2).

11. Endangered and Threatened Species of Flora and Fauna

As discussed above, the flaws inherent to the methodology employed by the Supplement (and the Draft EIS/EIR before it) to quantify loss of habitat poisons the entire analysis of impacts to biological resources and mitigation measures. These flaws overlap with and carry over to the Supplement’s analysis of impacts to endangered and threatened species and result in a great underestimation of impacts. Additionally, as discussed in our earlier comments, the methods employed by the Draft EIS/EIR, and now the Supplement, to determine the current population of certain endangered species results in overestimation of current populations, and thus, again, an underestimation of impact. September 2001 Comment Letter at 85.

Although the Supplement recognizes that existing wetland habitat for the Riverside Fairy Shrimp will be entirely destroyed by the Project, (Supplement at 4-485 and 4-486 to 4-487), it nevertheless both downplays the significance of this impact and also concludes that this impact will be fully mitigated by the creation of new habitat for the transplanted shrimp cysts off-site. *Id.* at 4-489 to 4-493 and 4-494. First, the Supplement fails to recognize that the current “degraded” nature of the Riverside Fairy Shrimp’s habitat is due to its own ongoing actions--grading and mowing the vernal pools the shrimp occupy. LAWA asserts that this destruction of habitat is necessary for maintenance purposes. Rather than recognize that this constitutes a “take” under the Endangered Species Act, the Supplement uses LAWA’s own improper actions to downplay the value of the habitat. Second, the Supplement and Appendix S-H offer little support for their assumptions that: (1) appropriate off-site habitat or land suitable for habitat construction will be found; (2) this land will be available for purchase; (3) money will be available for the purchase; and (4) the removal of the shrimp cysts from the Project site to this off-site location will be successful. Third, there is no discussion in the Supplement or the Draft EIS/EIR of the impacts that building this habitat off-site might

David Kessler
Jim Ritchie
November 4, 2003
Page 41

have to whatever environment is chosen for this new habitat. Given these problems and the lack of support for the document's underlying assumptions, the Supplement's conclusion that impacts to the Riverside Fairy Shrimp will be reduced to a level of insignificance is likewise unsupported.

Moreover, the Supplement fails to justify the decision to build an employee parking garage directly over the habitat for the Riverside Fairy Shrimp in the first instance. No explanation is given for why this structure could not be constructed on land that has already been disturbed for building. For example, the employee parking garage could be constructed nearby in the LAX west end where LAWA proposes to remove the existing remote aircraft gates. This option has not been explored, but should be, as a means of mitigation impacts to wetlands and endangered species.

Finally, as discussed in Section (10) above, because the Supplement employs a flawed methodology to quantify impacts to habitat, impacts to the El Segundo Blue Butterfly are greatly underestimated. Despite the construction of a number of new navigational aids and the loss of significant habitat for the butterfly, the Supplement concludes that the Project will not result in any significant impacts. *Id.* at 4-494. This conclusion is unsupported and premature.

12. Wetlands

The Supplement's analysis of impacts to wetlands and the mitigation proposed to deal with those impacts are inadequate for all alternatives. For further discussion of this issue, please see Section 11, above, (discussing impacts to vernal pools due to LAWA's ongoing "maintenance" procedures, impacts to the protected Riverside Fairy Shrimp, and the infeasibility of mitigating these impacts through off-site creation of replacement habitat), and our September 2001 Comment Letter (at 86).

13. Coastal Resources

Like the Draft EIS/EIR, the Supplement relies on the analysis and conclusions of earlier chapters, specifically, Sections 4.10 Biotic Communities and 4.11 Endangered and Threatened Species of Flora and Fauna, for its discussion regarding coastal resources. For the reasons set forth above in Sections 10 and 11, above, these analyses and conclusions are ill-supported and inadequate. The analysis of impacts to biological resources, including coastal resources, underplays and ignores significant

David Kessler
Jim Ritchie
November 4, 2003
Page 42

impacts to the coastal dunes ecosystem, including the habitat for the endangered El Segundo Blue Butterfly. Additionally, like the Draft EIS/EIR, the Supplement contains no discussion of impacts to marine life. Moreover, the build alternatives of the EIS/EIR, including Alternative D, remain inconsistent with the California Coastal Act, which requires that development projects protect, and where feasible, enhance the quality of the coastal zone environment. Pub. Res. Code § 30000 et seq.

14. Energy Supply and Natural Resources

As with other sections, the Supplement's analysis of energy supply and natural resources perpetuates the same problems seen in the analysis earlier presented in the 2001 Draft EIS/EIR. As such, the comments presented in our September 2001 Comment Letter remain salient and apply to the Supplement's analysis of Alternative D. In addition to those comments, we have identified the following problems with and notable issues raised by the Supplement's analysis of energy supply and natural resources:

- A significant portion of the numbers contained in Supplement Table S4.17.1-3 are marked with indicators explaining that those numbers have been modified from the numbers included in the 2001 Draft EIS/EIR in order to correct "errors" and "mathematical errors." The Supplement does not, however, provide any information regarding the nature or extent of those errors, does not explain why some changes are attributed to "mathematical errors" while others are simply called "errors," and does not provide any indication of why the errors occurred.
- The Supplement concludes that the impact of the Master Plan build alternatives (Alternatives A, B, C & D) on electricity and natural gas supplies would be less than significant because "a sufficient supply of electricity and natural gas is *expected* to be available." Supplement at 4-516 (emphasis added). In other words, the Supplement's analysis is based on an assumption that sufficient gas and electricity will be available to support the increased demand protected under Alternative D and the other Master Plan build alternatives. The Supplement cites no support for this assumption. As such, the conclusion that the Master Plan build alternatives' impacts on electricity and natural gas supplies would be less than significant is not based on substantial evidence. Project approval is therefore precluded under CEQA. Pub. Res. Code § 15091(a)-(b).
- The Supplement acknowledges that the increased demand for electricity projected

under Alternative D may result in the need to upgrade the electrical power transmission system. Supplement at 4-516. The document does not, however, identify any of those reasonably foreseeable transmission upgrade projects, much less evaluate the environmental impacts associated with their construction and operation.

- The Supplement notes that under Alternative D, “some” GSE and on-airport vehicles would be converted from gas/diesel to LNG, CNG or propane power. The Supplement must provide greater specificity with regard to this conversion. Such specificity is necessary in order to: (1) ensure the conversion program is actually carried out and enforceable; (2) accurately calculate the project’s energy supply impacts; and (3) accurately calculate the project’s air quality impacts (*see* Attachment 3).
- The Supplement concludes that Alternative D would entail a 412 percent increase in the consumption of LNG, CNG and propane over existing conditions. Supplement at 4-517. This is a major increase which, as even the Supplement acknowledges, would require construction of significant new distribution infrastructure. *Id.* The Supplement concludes, however, that the dramatic increase in the consumption of LNG, CNG and propane will not result in any significant environmental impacts. *Id.* This conclusion is not supported by substantial evidence because neither LAWA nor the FAA has adequately considered the environmental impacts of constructing and operating the new infrastructure necessitated by that increased consumption.

15. Solid Waste

The Supplement’s analysis of solid waste perpetuates the same problems seen in the analysis earlier presented in the Draft EIS/EIR. As such, the comments presented in our September 2001 Comment Letter remain salient and apply to the Supplement’s analysis of Alternative D. *See* September 2001 Comment Letter at 94.

In addition, one of the most obvious problems with the solid waste analysis in the Supplement is its reliance on an inaccurate solid waste generation factor. Specifically, the Supplement assumes a solid waste generation rate of 387 tons per million annual passengers (“tons/MAP”) despite the fact that this rate has previously proved to be overly optimistic (i.e., too low). *See* Supplement Technical Report S-7 at 2;

David Kessler
Jim Ritchie
November 4, 2003
Page 44

Supplement at 4-531. Year 2000 data shows, for example, that the actual generation rate was 431 tons/MAP rather than the 387 tons/MAP projected by LAWA for 2000 and future years. *Id.*

The only justification provided for the Supplement's reliance on this generation factor is the hopeful statement that "solid waste generation rates are expected to continually decrease and diversion is expected to increase at LAX." Supplement Technical Report S-7 at 2. This optimism is unfounded, however, in light of actual year 2000 data showing a higher generation rate and in light of the fact that LAWA, which is ultimately responsible for the amount of solid waste generated at LAX, has made inadequate "commitments" to reducing solid waste generation. As we noted in our 2001 comment letter, LAWA's various solid waste "commitments" lack the specificity and detail necessary to be enforceable, real and adequate. *See* September 2001 Comment Letter at 94. Commitment SW-1 described in the Supplement, for example, indicates that LAWA would implement a "more aggressive recycling program" but provides few details regarding the program and does not assess the likelihood of the program resulting in the significant solid waste generation factor reductions assumed by the Supplement. Supplement at 4-534.

16. Construction Impacts

The Supplement contains some new analysis of construction impacts, although the new information is not always easily identified. It continues to posit an overly optimistic construction schedule, rely on badly designed and unenforceable mitigation measures, and omit certain impacts of anticipated construction activity. As laid out above in our discussion of traffic impacts and in Attachment 2, the Supplement includes serious discrepancies regarding size of the workforce and the number of trips those workers would generate. As explained in our discussion of air quality impacts and in Attachment 3, the construction emissions analysis is significantly flawed and fails to disclose impacts on air quality from construction equipment and activity. In addition, the Supplement lacks an adequate analysis of construction noise. *See* Attachment 1.

Though the Supplement emphasizes that construction impacts are temporary, the proposed project would impose construction impacts on El Segundo and other neighboring jurisdictions for 10 years or more. These impacts will be severe, and LAWA and FAA must do a great deal more than they have in the documents to date to assure adequate mitigation of the noise, air pollution, traffic congestion, and other

David Kessler
Jim Ritchie
November 4, 2003
Page 45

impacts of the construction contemplated by this plan.

17. Art and Architecture

The analysis of impacts to design, art, and architecture found in the Supplement suffers from many of the same inadequacies as the previous discussion in the Draft EIS/EIR and is, thus, likewise inadequate. For our comments on the Draft EIS/EIR, which remain relevant here, please see our September 2001 Comment Letter at 100-102.

Additionally, the Supplement fails to describe any concrete or defined aesthetic and architectural standards to which the Project will be held. No discussion is provided regarding how architects and designers for the numerous individual building and landscaping projects will be chosen. Given the fact that this Project is one of the primary entrance points to California and the region for international and domestic travelers, and considering the significance and creativity of contemporary architecture in Los Angeles, standards should be established to ensure that talented and competent architects and designers will be chosen to design attractive, efficient, and highly functional buildings and environments.

Likewise, no building standards are described for the individual building and landscaping projects that will comprise the Project as a whole. For example, in order to mitigate some of the resource impacts this Project will likely entail, the Supplement and the Master Plan itself should require the incorporation of green building methods, practices, and materials. Such a commitment to green building, and a commitment to follow one of the recognized certification programs for green building, would show a commitment to the environment and improving the aesthetic and architectural character of LAX and its vicinity.

18. Earth/Geology

Because the Supplement relies on much of the same information and analysis found in the Draft EIS/EIR, our comments on the prior document remain relevant here, and apply to the analysis of Alternative D. September 2001 Comment Letter at 102-103.

Additionally, although the Supplement notes that the potential impacts due to earthquake fault surface rupture are higher for Alternative D as compared to the other

David Kessler
Jim Ritchie
November 4, 2003
Page 46

build alternatives, (Supplement at 4-584), little analysis of this condition is provided and no additional mitigation measures are offered. Instead, the Supplement concludes that, despite this increased risk, there remains no significant impact. This conclusion is not supported by fact or analysis. At the very least, additional analysis should be provided and further mitigation proposed to address the increased risk of fault surface rupture under Alternative D.

19. Hazardous Materials

The Supplement's analysis of hazardous materials perpetuates the problems pointed out in our September 2001 comments. Those comments remain salient and apply to the Supplement's hazardous materials discussion with regard to Alternative D as well. *See* Attachment 6 for our expert consultants' report on hazardous materials. As set forth in that report, the impacts of toxic contamination of soils and groundwaters on the LAX site on the health and safety of construction workers is a matter of grave concern. These impacts have still not been adequately analyzed; instead LAWA assumes, without analysis, that any such impacts will be mitigated. As explained in Attachment 6 and in Attachment F to our September 2001 Comment Letter, this approach is improper and the mitigation measures as proposed are legally deficient.

20. Public Utilities

Our comments on the Draft EIS/EIR pointed out numerous problems with the analysis of the impacts of the Master Plan alternatives on public services, particularly water and wastewater. *See* 2001 Comment Letter at 105-109. Although the Supplement claims to have corrected certain errors, many of the numerical discrepancies we noted previously (e.g., a water usage figure for Continental City that is at odds with the Draft EIR for that project) are repeated in the Supplement. Also evident in the Supplement is that by assuming that Alternative D would use water conservation methods and reclaimed water (without providing enforceable conditions to ensure this) the Supplement concludes that Alternative D would result in lower water usage than No Action/No Project Alternative. Supplement Table S4.25.1-1. This is not adequately documented, and there is no reason to assume that water conservation measures cannot be incorporated into the current airport without a new Master Plan. The analytical approach of the Draft EIS/EIR and the Supplement is flawed from a CEQA/NEPA perspective because it causes Alternative D to appear to have less severe water supply impacts than No Action/No Project Alternative by assuming that No Action/No Project Alternative will not comply

David Kessler
Jim Ritchie
November 4, 2003
Page 47

with conservation measures that are generally utilized in major public facilities; the result is a misleading comparison.

In this impact area as in others, LAWA's and the FAA's analytical assumption that Alternative D would serve a maximum of 78 MAP, when its gate capacity actually exceeds that and its terminal facilities and airfield capacity will be greatly expanded, leads to an erroneously low projection of water usage, and a resulting understatement of the impacts on water supply. Although the Supplement asserts that there will be adequate water supply for this project, the Los Angeles basin faces a chronic and severe water shortage, and the Master Plan alternatives' water supply impacts must be fully analyzed in the context of the cumulative water supply problems in the area. *See e.g., Stanislaus Natural Heritage Project v. County of Stanislaus*, 48 Cal.App.4th 182 (1996) (rejecting EIR for failure to analyze water supply aspects of development project).

Conclusion

The environmental impacts of LAX and the proposed airport improvement plans are massive. The plans for the airport's future should undergo detailed and accurate review, including full disclosure to the public and decisionmakers and an opportunity for the public to comment and be heard. For the reasons detailed in this letter and the attachments, and in our September 2001 Comment Letter and the associated attachments, the Draft EIS/EIR and Supplement still fail to provide adequate disclosure and mitigation of significant environmental impacts. Many of the problems identified in previous comments have still not been remedied. Additional analysis must be prepared to meet legal standards and adequate documents must be circulated to the public for review and comment.

LAWA and FAA may understandably be impatient to conclude this Master Plan process after many years of planning and review. The fact that this process has been a slow one, however, is not a justification for skimping on the necessary analysis and public disclosure. The Draft EIS/EIR should be corrected and recirculated to assure compliance with the legal requirements of CEQA and NEPA.

Very truly yours,

SHUTE, MIHALY & WEINBERGER LLP

CHRISTY H. TAYLOR

DIRECTOR OF REGULATORY AFFAIRS

GENERAL QUALIFICATIONS

Dr. Allen has over 28 years of technical and legal experience in aviation, engineering, environmental planning/analysis and document review. A substantial part of his career has been devoted to airport environmental studies, airport compatibility planning and analysis such as noise/land use, airspace modeling, aircraft accident potential, land use risk assessment and electromagnetic interference (EMI) studies. In recent years, Dr. Allen has also been involved in evaluating airspace issues and regulatory compliance under FAR Part 77 for telecommunications projects around the United States.

PROFESSIONAL EXPERIENCE

The following are specific areas of Dr. Allen's experience, including a few representative projects in each area:

Environmental Review and Analysis

Reviewed the Supplement to the Draft EIS/EIR on Airport Master Plan alternatives for Los Angeles International Airport on behalf of the cities of El Segundo and Inglewood. This Supplement principally addressed a new alternative proposed by Los Angeles Mayor James Hahn and augmented technical analyses on other alternatives requested by commenters on the Draft. This Supplement is subject to, and therefore reviewed for compliance with, both Federal (NEPA) and California (CEQA) requirements.

Reviewed the Draft EIS on the Airport Master Plan for Cleveland Hopkins International Airport on behalf of the City of Olmsted Falls which was concerned about the impact of the airport's expansion plans on their city.

Reviewed the environmental analyses and documentation developed by proponents of an international cargo use of Brown Field in San Diego on behalf of the City of Chula Vista. Major flaws were discovered in the document's disclosure of airspace and environmental implications of the proposal which ultimately resulted in the City Council of San Diego rejecting the proposal.

Reviewed and commented on the environmental documentation on noise-mitigating aircraft departure procedures at SEATAC Airport.

Directed the preparation of EISs pursuant to NEPA requirements for Airport Master Plans at Salt Lake City International Airport, Houston Intercontinental Airport, Los Angeles International Airport, Sacramento Metro, and Sacramento Executive Airports. In addition to NEPA requirements, the California Airports also are required to conform to the requirements of CEQA.

Prepared EIRs under CEQA for the introduction of new airline service at San Diego International and the introduction of MD-80 service at John Wayne Airport.

Prepared the EIS/EIR for "over the ocean" approach procedures at Los Angeles International Airport.

Prepared EIRs and impact assessments for wind energy conversion projects in California and Hawaii.

Regulatory Compliance

Reviewed approximately 5,000 telecommunications, broadcast and other development projects over the last 10 years for compliance with FAR Part 77, FAA Order 8360.2B, FAA Order 7400.2E and FAA Advisory Circular

70/7460-1K. Coordinated with both project proponents and the various FAA technical branches involved in the process.

Land Use Compatibility Studies

Analyzed the regulatory and legal issues involved with a major development project adjacent to Camarillo Airport. The principal issues involved FAR Part 77 compliance and the implications of an aviation easement still on the books from the days when Camarillo Airport was a U.S. Air Force Base.

Analyzed compliance of development projects adjacent to Chino Airport, Hemet-Ryan Airport and Bermuda Dunes Airport with the Airport Land Use Compatibility Plans prepared under California Law and also with a recent publication on the current thinking on Airport Land Use Compatibility Planning by the California Department of Transportation.

Directed and conducted land-use compatibility plans at airports across the nation, including Salt Lake City, Reno, Houston, Oklahoma City, San Diego, Milwaukee, and Hartford. These plans were developed pursuant to the FAA's pilot program called Airport Noise and Land Use Compatibility (or ANCLUC) and its successor FAR Part 150.

Conducted EIRs and land-use assessments pursuant to California law for heliport projects at Brea, Huntington Beach, and Anaheim, and for helicopter airline service at John Wayne, Los Angeles International, Ontario, and Burbank-Glendale-Pasadena Airports.

Developed land-use compatibility guidelines for the general plans of 2 counties and 16 cities in California.

Noise Studies

Conducted computerized noise studies using the FAA's Integrated Noise Model (INM) or the DOD's NoiseMap Model at hundreds of airports across the United States, including Los Angeles International, Houston Intercontinental, John Wayne (Orange County), San Diego, Jacksonville, Norton Air Force Base (Civilian Re-use), NAS Agana Guam (Civilian Re-use), Kalamazoo, Santa Maria, Salem, Ontario, Tacoma, Fort Worth, Gainesville, Salt Lake City, Milwaukee, Bellingham, Port Angeles, Rialto, Banning, Shelton, Sacramento, Oklahoma City and Burbank-Glendale-Pasadena Airport.

Designed and conducted field noise monitoring surveys to validate the accuracy of computer modeling or to confirm noise complaints at Houston, Salt lake City, Palomar, and Aspen.

Conducted noise assessments, including substantial field noise monitoring, for proposed new heliports at Victorville, San Bernardino, Sarasota, Baldwin Park, Brea, Huntington Beach, and Anaheim, California, and for new helicopter service at John Wayne, Los Angeles International, Ontario, and Burbank-Glendale-Pasadena Airports.

Developed the noise assessment portion of the "Planning Guidelines for Helicopter Facilities in the San Diego Region," which was used by the local association of governments (SANDAG) to assess heliport proposals in the region.

Directed or conducted airport noise abatement plans at airports across the nation, including Salt Lake City, Reno, Houston, Oklahoma City, San Diego, Milwaukee, and Hartford.

Developed noise contours for the DOD using NoiseMap as part of Air Installation Compatible Use Zone (AICUZ) studies at MCAS Kaneohe Bay, NAS Barbers Point, NAS Agana, NAS Alameda, NALF San Clemente Island, OLF Imperial Beach, USCGS Elizabeth City.

Analyzed noise effects from institution of new noise abatement takeoff procedures at John Wayne Airport on behalf of Newport Beach.

Directed acquisition of aircraft operations data for noise studies at Marine Corps Air Station El Toro and Naval Air Station Pt. Mugu.

Reconstructed noise environment on west-end of Ontario International in the 1970-1976 era for purposes of litigating a malpractice complaint.

Air Quality Studies

Managed air quality studies for airport EIRs at Los Angeles International, John Wayne, Ontario, Santa Maria, Oxnard, Camarillo, Houston Intercontinental, Rialto, and various other airports. Under contract with the FAA, directed microscale analysis of second level roadway at Los Angeles International Airport.

Managed over 100 air quality assessments for general plan amendments, highway projects, airport expansion projects and private residential and commercial development projects throughout California and Nevada.

Directed air quality assessments for supplemental EIRs for the City of Los Angeles General Plan/Zoning Consistency Program. Directed air quality studies for hotel expansion and the residential projects in the Truckee Meadows airshed.

Conducted analysis of obstruction of sea breeze windflow by proposed residential project in Dana Point. Analyzed air quality implications of Irvine General Plan Update. Analyzed air quality implications of alternative land-use concepts in Aliso Water Management Agency territory.

OTHER PROFESSIONAL EXPERIENCE

Successfully litigated (as second chair) a contractual dispute between a Mexican Air Line and an aircraft leasor.

Was a pioneer in the development of airport noise/land-use compatibility plans and has been heavily involved over the years in the development of noise elements for community general plans.

Was instrumental in the development of wind turbine noise assessment and authored several papers and over 200 project reports on wind farm noise impacts.

Authored book on Environmental Evaluation of Airport Site Selection Alternatives.

Conducted FAA-approved computer modeling studies on the electromagnetic interference potential of FM stations on airport navigational aids at dozens of airports across the nation.

Conducted aircraft accident potential studies on development proposals adjacent to John Wayne, Camarillo, Riverside, Bermuda Dunes and French Valley Airport.

Conducted airspace modeling of civilian re-use of Norton Air Force using SIMMOD

Served as expert witness in airport noise/land use compatibility litigation.

EDUCATION

J.D. Law, Western State University College of Law.

PhD Environmental Science (Aviation emphasis), California Western University.

M.S. Environmental Studies (Aviation emphasis), California State University, Dominguez Hills.

M.S. Environmental Systems Management, West Coast University.

B.S. Engineering, Northrop University.

Certificate in Urban Planning, University of California, Irvine.

Certificate in Environmental Impact Reporting and Evaluation, University of California, Irvine.

Coursework in Airport Planning, University of California, Berkeley.

October 13, 2003**

Acoustical Review of the Supplement to the Draft EIS/EIR for the LAX Master Plan

Introduction

We have reviewed portions of the *Supplement to the Draft Environmental Impact Statement/Environmental Impact Report (EIS/EIR)* for the LAX Master Plan to identify acoustical issues that may be of concern to adjacent communities to the east and south of LAX. These portions of the Supplement include Chapter 4.1, *Noise*, and Appendix S-C1, *Supplemental Aircraft Noise Technical Report*.

General Comments

The Supplement does address some of the deficiencies in the Draft EIS/EIR; in particular, it adds information about the Year 2000 in addition to the Year 1996. That year (2000) is generally thought to be more appropriate for the environmental baseline than 1996 because using 1996 gives the Airport Master Plan the perception of more noise reduction than it should be credited with. The Federally mandated phase-out of Stage 2 aircraft, which is unrelated to the Master Plan, is actually the cause of a significant noise reduction between 1996 and 2000. However, the Supplement, while revealing that noise levels in 2000 were lower than 1996, still uses 1996 as the baseline for evaluating impacts.

The Supplement also adds information that purports to comply with the California Court of Appeals decision in Berkeley Keep Jets over the Bay Committee v. Board of Port Commissioners, to document single event noise effects on the surrounding communities. The problem is that the single event noise information in the Supplement is presented in ways that obfuscate rather than clarify the impact. Rather than provide SEL contours for each of the aircraft types operating at LAX and their frequencies of occurrence, which would provide meaningful information to the lay reader, the Supplement provides an artificial contrivance (the so-called 94 dB SEL contour) which is based on an arbitrary assumption of what a significant percentage of nighttime awakenings is. While this method of correlating SELs and awakenings is interesting it doesn't really answer the questions residents continually want to have answered, i.e., how noisy will the overflights be and how many times am I going to hear them? Outside the airport and the mathematical world of noise analysis, the communities and their residents have a perceived severe annoyance with overly intrusive aircraft noise. And, the annoyance is not just awakenings but also interference with speech and other activities, both indoor and outdoor.

Speech Interference

The Supplement does not address speech interference associated with aircraft noise although, like sleep disturbance, it is a primary cause of annoyance to individuals on the ground. It disrupts routine activities such as radio or television listening, telephone use, and family conversation giving rise to frustration and aggravation. According to both the U.S. Environmental Protection Agency in its seminal "Levels Document" Information on Levels of Environmental Noise Requisite to Protect Public Health and Welfare with an Adequate Margin of Safety EPA 1974 (Figure D-3, pg D-7) and the Federal Interagency Committee on Noise (FICON) document Federal Agency Review of Selected Airport Noise Analysis Issues FICON Federal Inter Agency Committee on Noise Aug 1992 (pg 3-7) "wherever intrusive noise exceeds approximately 60 dB indoors, there will be interference with speech communication." It can be reasonably concluded that outdoor noise exceeding (roughly 75 dB) will also cause this intrusive interference. The Supplement like its predecessor Draft EIS/EIR is silent on this issue despite the fact that residents of El Segundo and other communities surrounding LAX are affected daily by this annoyance factor. To provide meaningful information on all aspects of annoyance, the Supplement should utilize and disclose a 75 dB SEL contour like the one developed for the awakenings aspect of annoyance. Likewise, assuming 60 dB events will also affect outdoor communication, a 60 dB SEL contour should be provided to the communities around LAX.

Flights Above 3000 Feet

On another but related vein, the Supplement continues to ignore flight operations above an altitude of 3,000 feet Above Ground Level (AGL), relying on FAA Rules that categorically exclude such flight operations from environmental review under NEPA. However, FAA Order 1050.1D prescribes that "extraordinary circumstances" such as actions which are likely to have a significant impact on noise levels over noise sensitive areas, or a significant impact on coastal zones, "shall be the subject of an environmental assessment." The Supplement, as did the Draft EIS/EIR, appears to be based on the faulty premise that noise in the South Bay communities which lies outside the parameters established for the noise analysis, does not exist. The noise analysis is, obviously, deficient with respect to its treatment of these areas. There are, in fact, several points that will be discussed later that will have a material impact on residential areas and coastal zones and the "extraordinary circumstances" exception should be applied. As stated above, FAA Order 1050.1D calls for at least an assessment of changes in operations above 3,000 feet AGL. Nevertheless, the Supplement and its predecessor Draft EIS/EIR simply dismiss this requirement categorically stating that "no further noise review" above 3,000 feet is necessary since the noise associated with jet aircraft weighing more than 75,000 pounds will not change more than five decibels CNEL. The rationale for this five dB CNEL standard is apparently derived from FAA Notice 7210.360 which states that below 60 dB DNL an increase of 5 dB is only a "marginal" impact. Other than that there appears to be no basis for it.

Furthermore, the Supplement and the Draft EIS/EIR misconstrue the FAA's benchmark for the measure of overflight as "Above the Airport" when actually it is "Above Ground Level" (AGL). Obviously, the Supplement's use of "3,000 feet above an airport's elevation," as the criterion places communities in the South Bay and elsewhere which are located well above

the airport's elevation at a severe disadvantage. For instance, Palos Verdes is at approximately 1,480 feet elevation, while the Airport is located at 126 feet. Due to the difference in elevation between Palos Verdes and the Airport, an aircraft may be 3,001 feet "above the airport", and its noise not subject to environmental review under LAWA's theory, while it is only 1,521 feet above Palos Verdes. Thus, while the noise impact may not meet the "above airport" criterion, the noise over Palos Verdes would be significantly greater than assumed, but remain unaccounted for in the model. There is no doubt about this since the Supplemental Aircraft Noise Technical Report on page 33 states that for purposes of consistency with the Draft EIS/EIR the Supplement relied upon the FAA's Air Traffic Noise Screening Model (ATNS) described in FAA Notice 7210.360 to "assess the effects noise level changes associated with air traffic procedure changes at altitudes greater than 3,000 feet above an *airport's elevation* [clearly misconstruing the FAA's intent]. This methodology requires that changes in aircraft noise be evaluated if the noise associated with jet aircraft weighing more than 75,000 pounds changes by more than five decibels of DNL (CNEL in California) over residential areas and the aircraft is in flight at an altitude between 3,000 and 18,000 feet *above the airport*." Whether or not the preparers of the Draft EIS/EIR actually used the current computerized version of FAA Notice 7210.360 was called into question during the comment period for the Draft and the Supplement does not provide any evidence of an update. In fact, it appears that use of the outdated and obsolete checklist from the former FAA Notice 7210.360 was continued, leading to the Supplement's reaffirmation on page 33 of the Draft EIS/EIR assertion that "since the flight tracks of the new and relocated runways will be located within close proximity to the present flight tracks of the existing runways, and the aircraft activity on these tracks will not result in an increase of 5 decibels of DNL (CNEL) over any residential area when the aircraft are above 3,000 feet, [*the checklist*] indicates that no further noise review under this guideline is required." Without doubt the Supplement perpetuates the Draft EIS/EIR's misleading the public into believing that an actual, scientific analysis was conducted to determine whether noise would increase above 3,000 feet when it was not.

Single Event Noise Analysis

The remedy for many of the Supplement's shortcomings is a complete, accurate and understandable SEL analysis. However, the Supplement, as earlier the Draft EIS/EIR, emphasizes the cumulative time-averaged aircraft noise impacts created by aircraft approaching LAX from the east and from start-of-takeoff roll for west departures. Despite the contrived 94 dB SEL that appears in the Supplement, the Supplement simply doesn't provide any meaningful information either. It still fails to depict and analyze the SELs from potential routes over areas not previously over-flown, from missed approaches and it still does not address a potential increase in lateral separation of aircraft which could lead to an increase in overflight noise. It cavalierly dismisses this concern alleging the flight tracks will not significantly change (Aircraft Noise Technical Report, page 20). However, the Airport Master Plan on pages 11-2.36 and 2.37 indicates that when LAX is operating on a west flow, turbo-prop aircraft turn at the VOR (or Visual Omni Range) navigational aid despite the policy statement and noise abatement procedures which require aircraft to proceed past the shoreline before starting a turn. If the turbo-prop aircraft do turn early, as the Master Plan indicates and as South Bay communities continue to insist, they will obviously fly over noise

sensitive areas such as parts of El Segundo, thus falling under the “extraordinary circumstances” exception mentioned above and requiring further analysis. The Supplement weakly addresses this issue with some well-hidden Lmax data that falls well short of providing any meaningful information (id, Table S15, pages 78-88). The Supplement should provide SEL contours for each aircraft type on each flight track and their frequency of occurrence.

Other General Comments

Although Alternative D, which is the Preferred Alternative in the Supplement, does not postulate an increase in air traffic operations above the baseline or the No Action/No Project Alternatives, the other study Alternatives still forecast an increase in operations. As the Draft EIS/EIR before it, the Supplement does not clarify how these increased operations will be integrated into the existing Airport air traffic flows nor that they have a real-world potential for increased overflights of South Bay communities.

To accommodate this increase in air traffic, more airspace will probably be required to maintain adequate separation between aircraft during climb out. Air traffic controllers separate aircraft in two ways, laterally and vertically. Generally speaking, heavy departing aircraft are dispersed laterally. As lateral separation between departing aircraft must be maintained, a greater number of offshore aircraft may come closer and over the shoreline, which may also lead to premature easterly turns from the initial southerly headings of departing flights. These premature turns will potentially lead to an increase in overflight noise over South Bay Communities and should be addressed in the Supplement’s coverage of the other Alternatives.

The South Bay Coastal Zones are a resource of not only local significance but also state and national significance. Relying on the Extraordinary Circumstances exception the Supplement should provide a meaningful analysis of impacts on South Bay coastal zones.

The noise standards for El Segundo and other surrounding communities were not considered when establishing significance criteria for the impact analysis which seems an extraordinary omission since these communities are undisputedly affected by whichever action is ultimately taken by LAWA.

No attempt appears to have been made to check the accuracy of the input data to the INM noise model or to correlate it to actual operational conditions at LAX and not even to calibrate it to noise measurements in the area. As a result, the aircraft noise levels cited in the Supplement may be in error as much as 3 dB. This may not seem like much but it actually represents up to twice the noise energy and should not be trivialized.

The significance criteria developed by LAWA for nighttime awakenings are not only arbitrary but also may not have been properly analyzed or assessed.

The impact of single event aircraft noise levels at schools in the airport environs may not have been properly defined, analyzed or assessed.

The impact of roadway noise levels may not have been properly analyzed or assessed.

Specific Comments on Chapter 4.1 of the Supplement, Noise

The discussion of aircraft noise and its impacts in Chapter 4.1 of the Supplement are presumably based on the analysis provided in Technical Appendix S-C1, *Supplemental Aircraft Noise Technical Report*. Any concerns with the analysis and assessment of aircraft noise are, therefore, discussed in our review of the technical appendix in the next section of this report. The following comments on Chapter 4.1 are limited to issues other than aircraft noise, except in those cases where the text of Chapter 4.1 differs from the analysis provided in the technical appendix.

1. The community standards for noise, as established in the noise ordinances and noise elements of El Segundo and other cities surrounding LAX, were not considered when establishing significance criteria for the project. One would think that if you are proposing an action that will affect surrounding communities that you would consider what they perceive as an impact.
2. There is no discussion regarding mechanical equipment or activity noise levels that may occur at the new buildings on the south side of LAX, and their potential impact on noise-sensitive communities in El Segundo.
3. In Section 4.1.2.1.2, the text states that the peak hour of airport operations during school hours was used to assess the impact of aircraft noise on schools. While this is the proper approach (based on the thresholds of significance established for the project), it is clear in Technical Appendix S-C1 that an *average* of eight school hours was used in the analysis, not the *peak* hour (id, page 150 and Table S31).
4. In Section 4.1.2.1.2, the text states that a “Time Above” threshold was used to evaluate noise impacts at schools. This was not identified as a significance criterion in the technical appendix.
5. In Section 4.1.2.1.3, the text states that peak *noise* hour data (i.e., data for the noisiest one-hour period of the day) were used in the analysis of traffic noise. However, based on our review of Technical Appendix S-C2, *Roadway Noise Data*, it appears that either peak AM or PM traffic data were used. These traffic peak hours are not typically the noisiest hours of the day since traffic slows due to congestion, and slower traffic is not as loud. So the analysis understates traffic noise. It appears that the data in Technical Appendix S-C2 also reduces traffic speeds for future years, which could also result in understating noise impacts.
6. In Section 4.1.2.1.3, it isn’t clear why traffic and aircraft noise were converted to a 24-hour Leq metric for combining, rather than simply converting the traffic noise to a CNEL

metric for combining with the already computed aircraft CNEL. This convoluted manipulation is an unnecessary step and further adds to the confusing nature of the impact data presentation.

7. In Section 4.1.3.1.2.1, the analysis of nighttime awakenings may be incorrect. Refer to the review of Technical Appendix S-C1 in the following section of this report.
8. In Section 4.1.3.1.2.2, the text states that the peak hour of airport operations during school hours was used to assess the impact of aircraft noise on schools. While this is the proper approach (based on the thresholds of significance established for the project), it is clear in Technical Appendix S-C1 that an *average* of eight school hours was used in the analysis, not the *peak* hour.
9. In Section 4.1.3.2, again, it isn't clear why traffic and aircraft noise were converted to a 24-hour Leq metric for combining, rather than simply converting the traffic noise to a CNEL metric for combining with the already computed aircraft CNEL.
10. In Section 4.1.3.2, no methodology or calculations are provided to indicate how a one-hour Leq for traffic noise was converted to a 24-hour Leq.
11. In Section 4.1.4.1, the Lmax thresholds for assessing aircraft noise impacts in schools can be related to existing studies, but the 3-second "Time Above" criterion appears to be arbitrary and isn't even mentioned in the Aircraft Noise Technical Report. It isn't clear whether the criterion is cumulative for a school day or for the peak hour, or whether it applies to each individual aircraft event.
12. In the significance criteria for roadway noise used in the Supplement (i.e., a peak hour 5 dBA Leq(h) increase over existing conditions and 67 dBA Leq(h) for new facilities resulting from this project as compared to existing conditions) are inconsistent with the CNEL standard used in the Supplement and Draft EIS/EIR to assess aircraft noise, and are inconsistent with the local community standards for addressing traffic noise impacts.
13. In Section 4.1.6.1.5.4.1 regarding nighttime awakenings, the analysis is flawed. Refer to the our comments on the Technical Appendix S-C1 in the following section of this report.

Specific Comments on the Technical Appendix S-C1, Supplemental Aircraft Noise Technical Reports

1. In Section 1.3, the text states that the Draft EIS/EIR was prepared with INM 6.0 model and that the Supplement to the Draft EIS/EIR was prepared with the INM 6.0c model. However, the Draft EIS/EIR, Appendix D, page 6, discusses Version 5.1a...so, which is it? In any case, since the versions use slightly different databases for aircraft noise, it is important to either use the same version of the model, or to ensure that both versions

produce the same results for LAX. Furthermore, in neither case, the Draft using INM 5.1a or 6.0 nor the Supplement using INM 6.0c was the INM's topographic module used in conjunction with the basic noise computation function. In other words, the topography of the area overflown by LAX flights was not considered at all in determining CNEL or SEL values. In the flatter areas under the approaches and along the South Bay beach communities, that omission is of minor consequence but it significantly underestimates the noise predicted for higher terrain in the South Bay such as the Palos Verdes Peninsula. That is why the residents of the Peninsula consistently dispute the noise impacting their communities. The Supplement and the earlier Draft dismiss this as an irrelevant concern because the aircraft are higher than 3,000 feet above the airport reference point as they overfly those areas. However, FAA Order 1050.1D mandates that "extra ordinary circumstances" such as actions likely to have a significant impact on noise sensitive areas or coastal zones "shall be the subject of an environmental assessment." The Palos Verdes Peninsula seems to fit easily within that requirement. Overflights of Palos Verdes, for example, which is approximately 1,480 feet elevation may well be within 3,000 feet above ground level (which is the proper basis for analysis rather than the airport reference point) and should be considered in the impact analysis. Using the topographic module and enlarging the study area to include the Peninsula should remedy this glaring analytical problem. At the very least, the FAA's Air Traffic Noise Screening Model should be applied to the Palos Verdes Peninsula rather than cavalierly dismissing the residents' concerns although this model only addresses one specific part of the problem, i.e., aircraft over 75,000 pounds.

2. In Section 2.1, the text states that the LAWA software automatically assigns an aircraft to a flight track and to an INM aircraft type. It isn't clear that there is any radar tracking to verify the flight tracks, nor is it clear that the aircraft types are being assigned properly (e.g., "light" vs. "heavy" aircraft). Residents of the communities south of LAX have been consistently claiming that many aircraft turn south before crossing the shoreline as is required by the Airport's FAR Part 150 Noise Control Plan.
3. In Section 2.1.4, the text states that a 3° glide path has been assumed for all approaches. While that may be what appears in the Jeppeson charts, it isn't clear in this section that this is consistent with actual operations at LAX.
4. In Section 2.1.5, the average number of aircraft operations by aircraft type and time of day were estimated on a proportional basis using the 85% of operations that were actually monitored by the LAWA software. No attempt appears to have been made to determine if this approach yields data that is consistent with actual operations at the airport.
5. In Section 2.1.7, the text admits that the INM under-predicts the CNEL by 0-3 dB based on noise monitoring around LAX. Therefore, it may be reasonably concluded that the CNEL, SEL and Leq analyses for Alternative D are also under-predicted by the same 0-3 dB. (The INM model uses SEL values to calculate CNEL, so an under-prediction of one reflects an under-prediction of the other. Leq is likewise related to SEL and CNEL). A deviation of 3 dB is significant, as alluded to in the significance criteria used for

assessing airport noise impacts. In fact, it represents an enormous difference in the noise energy impacting on the airport's environs. While the Supplement to the Draft EIS/EIR cannot ethically alter the contours to account for the measurements, apparently no attempt was made in the Supplement to ensure the accuracy of the myriad input data (e.g., flight track definitions, flight profiles, operations distributions on the various flight tracks, etc.) for the INM model to help calibrate the model to the actual conditions and obtain more consistency with the measurements. Moreover, the INM's basic noise curves are based on noise certification measurements taken under specific atmospheric conditions (temperature and humidity) that are not consistent with those existing at the near-sea level LAX and its environs. The model supposedly adjusts for local conditions but uses an annual average for temperature and, according to this section, uses default humidity. It is no wonder that the model contours and the measurements are not consistent.

6. In Section 3.1.5, the text states that during the construction of Runway 7R/25L, the noise contours near the south set of runways will be shifted about 1/8 mile to the North for a period of one year. As a result, noise-sensitive locations that were outside the 65 dB contour line will be exposed to a CNEL that is up to 5 dB higher. No mitigation measures are identified for the construction phase aircraft noise impacts.
7. In Section 3.1.6, the text states that the extension of Runway 24L to the East will create a bulge in the contours, exposing noise-sensitive locations in east-lying communities that would not otherwise be exposed to a CNEL of 65 dB. No mitigation is identified for this impact.
8. In Section 3.1.6, the text states that Alternative D will shift the northern portion of the noise contours by 100 feet to 500 feet to the South and will shift the southern portion of the contours 50 feet closer to El Segundo. No mitigation is identified for this impact. Section 3.1.3 alleges that there would be no appreciable difference in the CNEL in El Segundo in comparison to the No Action/No Project Alternative. Of course, the report does not indicate the effect on SELs which would logically be slightly higher.
9. Table S14 provides the aircraft noise analysis results in terms of DNL, not CNEL. Therefore, the CNEL impacts identified in Table S20 cannot be corroborated.
10. Table S15 identifies the anticipated Lmax noise levels generated by aircraft operations. No comparison with the results from noise monitoring stations surrounding LAX appears to have been made to determine the accuracy of the INM model in predicting Lmax levels.
11. In Section 5.0, there is no identification of impacts on residential properties.
12. In Section 6.1.1, the significance threshold established by LAWA for nighttime awakenings is 10% of the population being awakened no more than once every ten days. The report claims that this is statistically equivalent to 1% of the population being awakened every night. However, this is not only completely arbitrary but also incorrect.

A threshold of 1% of the population being awakened every night is far more stringent than 10% of the population being awakened no more than once every ten days.

13. In Section 6.1.2, the description of the methodology used to calculate the location of the 94 dB SEL noise contour is unclear. Using the 94 dB SEL criterion, itself, is completely arbitrary since it is merely correlates to a point on a noise data trend line where the 1997 FICAN report states that 10% of the population exposed to this level will be awakened. Why 10% is selected as the benchmark is unknown. To establish a noise contour for operations that would occur once every ten days, it appears that the methodology only considered aircraft operations that occur at least 0.1 times per day (or once every ten days). If this is a correct understanding of the methodology, then the methodology is in error. The fact that the methodology includes only aircraft that have at least 0.1 operations per day means that some operations have been *excluded* from the analysis. This could mean that infrequent takeoffs to the east under Santa Ana conditions were not considered in the analysis. This would have a significant effect on the residents in eastern communities including Inglewood. In effect, what is plotted in the Supplement is the 94 dB SEL contour (i.e., the contour for 10% awakenings) for a subset of the total operations occurring at the airport. Thus, the analysis is incorrect for two reasons: (1) it plots the contour for 10% awakenings, not 1%; and (2) it under-predicts the contour because it does not include all of the flight operations at the airport. It should also be noted that, as indicated in Comment #5, above, the model under-predicts SEL values by 0-3 dB. This was not considered in the analysis or assessment of impact. Furthermore, the technical report concludes that 10% of the people living on the 94 dB SEL contour line will be awakened once every 10 days ignoring the fact that the people living "inside" that 94 dB SEL contour line will be exposed to even higher SELs and the actual total percentage of awakenings will be substantially higher.
14. In Section 6.1.2, it isn't clear that the analysis of nighttime awakenings only included nighttime aircraft operations. It also isn't clear that ground run-up operations were included in the analysis.
15. The analyses and findings discussed in Sections 6.1.2.1 and 6.1.2.2 may be incorrect based on Comments #12 and #13, above.
16. In Section 6.1.3, the mitigation for nighttime awakenings is filing a 14 CFR Part 161 application. However, as the text states in Section 3.1.6, this application will only eliminate a pilot's discretion for nighttime takeoffs to the east. For safety reasons, takeoffs to the east will still occur during Santa Ana conditions or when coastal fog limits visibility. Since these safety reasons account for the great majority of takeoffs to the east (as stated in Section 3.1.6), the 14 CFR Part 161 application will provide little mitigation to the residents of communities east of the airport.
17. In Section 6.1.3, the text states that the 14 CFR Part 161 application will only apply to eastbound takeoffs between midnight and 6:30 a.m. However, Section 6.1 states that the analysis of nighttime awakenings applies to the hours between 10:00 p.m. and 7:00 a.m.

Therefore, the proposed mitigation measure will not be effective for a period of 2-1/2 hours each night.

18. Because of Comments #12, #13, and #15 through #17, the sound insulation program identified in Section 6.1.3 may be inadequate in terms of the area covered by the program.
19. In Table S33, the average Leq for the 8-hour school day is obtained by adding $10\log(3)$ to the 24-hour Leq calculated by the INM model. The basis for this calculation appears to be that the 8-hour school day is 1/3 of a 24-hour day. However, this methodology is incorrect since flights are not evenly distributed throughout the day. The result of the analysis is an average Leq that is too low because most flights at LAX occur during the daytime. It should be noted that, as indicated in Comment #5, above, the model under-predicts Leq values by 0-3 dB. This was not considered in the analysis or assessment of impact. It should be further noted that, as indicated in Chapter 4.1 of the Supplement, the analysis should have been based on the *peak*, not *average*, hour.
20. In Section 6.2.3, the text states that the current eligibility for school mitigation is based on CNEL. But this is unrelated to Section 6.2 which is an analysis and assessment of single event noise levels, not CNEL, at schools. An appropriate mitigation measure would be to revise the eligibility requirements to include the new single event criteria.
21. In Section 6.2.3, the only mitigation proposed for the single event criteria at schools is an additional study to determine whether the criteria used are appropriate. This is not reasonable. LAWA has identified what it considers to be appropriate significance criteria based on several existing studies on the issue of classroom disruption. Therefore, concrete mitigation measures should be identified to mitigate the significant impacts identified in the report.

SUBJECT: Review of the Traffic Impacts of the Los Angeles International Airport Master Plan "Alternative D – Enhanced Safety and Security Plan"

Dear Ms. Taylor:

Tom Brohard, PE, has reviewed various reports and documents associated with the Los Angeles International Airport (LAX) Master Plan prepared for Los Angeles World Airports (LAWA) and the Federal Aviation Administration (FAA.) These include, but are not limited to, the June 2003 LAX Master Plan Addendum and the July 2003 Supplement to the Draft Environmental Impact Statement/Environmental Impact Report (Supplement.) Our review focused on the traffic impacts of Alternative D upon the City of El Segundo as identified in various documents and reports, particularly in S-2b, the Supplemental Off-Airport Surface Transportation Technical Report prepared by Parsons Transportation Group in June 2003. The comments in this letter are in addition to our July 16, 2001 report prepared for the City of El Segundo regarding the traffic impacts of LAX Master Plan Alternatives A, B, and C. LAWA and FAA have not yet responded to those earlier comments, and many of the problems with the analysis previously identified have not been addressed.

In summary, LAWA has not conducted an adequate traffic and circulation analysis of Alternative D. Without further study to address the inadequate analysis and substantial evidence of significant traffic impacts, as discussed below, it is not legally permissible to conclude, as the Supplement does, that most of the proposed project's traffic impacts have a less than significant effect on the environment with mitigation. A corrected traffic analysis for Alternative D must be prepared, and the Supplement for the Los Angeles International Airport Master Plan must be revised and recirculated, to address these critical issues.

Education and Experience

Since receiving a Bachelor of Science in Engineering from Duke University in Durham, North Carolina in 1969, I have gained over 33 years of professional engineering experience, all of which has occurred in California. I am licensed as both a Professional Civil Engineer and as a Professional Traffic Engineer in California. I formed Tom Brohard and Associates in 2000 and now serve "on call" as Consulting Transportation Engineer for the City of Huntington Beach.

Ms. Christy H. Taylor
LAX Master Plan Alternative D Traffic Comments
October 28, 2003

I have extensive experience in traffic engineering and transportation planning. During my career in both the public and private sectors, I served as City Traffic Engineer for the Cities of Bellflower, Bell Gardens, Huntington Beach, Lawndale, Los Alamitos, Oceanside, Paramount, Rancho Palos Verdes, Rolling Hills, Rolling Hills Estates, San Marcos, Santa Ana, and Westlake Village. While serving these communities, I personally conducted many investigations of citizen requests for the installation of various traffic control devices. During these assignments, I successfully presented hundreds of traffic engineering reports at City Council and Traffic Commission meetings. During my career, I have also reviewed numerous environmental documents and traffic studies for various projects. My most recent work is highlighted in the enclosed resume.

Brief Summary of the Project

According to the Project Description on Page 3-2 of the Supplement, Alternative D is proposed to include facilities designed to serve 78.9 million annual passengers (MAP) and 3.1 million annual tons (MAT) of air cargo activity. The Supplement indicates "this level of aviation activity is also equivalent to the No Action/No Project activity level, which is projected to accommodate approximately 78.7 MAP and 3.1 MAT of air cargo." Page 3-57 of the Supplement indicates Alternative D is now the preferred alternative.

Page 3-43 of the Supplement describes the facilities in Alternative D as follows:

"Alternative D retains the existing four runway configuration at LAX. Major project elements include airfield modifications, the development of new terminals with the removal of public parking structures in the existing CTA and elimination of private vehicle access to the CTA. It also includes a Ground Transportation Center (GTC), Consolidated Rental Car Facility (RAC), Intermodal Transportation Center (ITC), and an Automated People Mover (APM) system."

LAX Master Plan Addendum Traffic Related Issues

The following concerns, omissions, and deficiencies relate to the traffic impacts associated with Alternative D upon the City of El Segundo. These comments were developed during our detailed review of the traffic related portions of the LAX Master Plan Addendum.

1. LAX Will Continue to Experience Pressure to Grow – Page 2-1 indicates "Alternative D would be designed to serve approximately 78 MAP" and "The Alternative D design would encourage other airports in the region to develop facilities to accommodate regional demand beyond the level served at LAX." Table 1.3-2 indicates LAX could be expected to attract about 98 million annual passengers with the other regional airports serving about 48 million annual passengers. With the removal of El Toro as a potential secondary

Ms. Christy H. Taylor
LAX Master Plan Alternative D Traffic Comments
October 28, 2003

airport for the region and with various constraints associated with each of the other existing secondary airports, LAX will continue to experience significant pressure to expand beyond the 78 million annual passengers. Serving more than 78 million annual passengers will result in additional traffic impacts to the freeways and street intersections above those identified in the Supplement.

2. Larger Aircraft in 2015 Results in Significant Passenger Increases – Table 2.2-2 compares the type of gate positions for various aircraft in 2002 with those proposed in 2015. The trend in this table clearly indicates larger planes with more passengers per plane will serve LAX in 2015. Page 2-9 indicates the design aircraft include the Boeing 747-400 for Group V and the Airbus A380 as a representative aircraft for Group VI, also known as New Large Aircraft. Larger aircraft with 500 to 600 or more passengers per plane result in more vehicle trips and additional traffic impacts to freeways and streets above those identified in the Supplement.
3. Number of Gates Is Not Legally Constrained – Table 2.2-3 compares the number of gates by aircraft group type between Alternative D and the No Action/No Project. While the text on Page 2-32 indicates Alternative D would discontinue the use of remote gate positions, there is nothing presented in the Master Plan which would guarantee the elimination of these gates or that would prevent the establishment of other remote gates at LAX. An increase in the number of gates beyond the 153 that have been assumed in Alternative D would result in more passengers, more vehicle trips and additional traffic impacts to freeways and streets above those identified in the Supplement.
4. Unsupported Passenger Assumptions Significantly Understate the Impacts – Page 3-5 indicates “The ability to increase aircraft size, thereby increasing passenger levels, was limited by the number and types of gates available under the Alternative D terminal design.” As indicated in comments above, more gates serving larger aircraft will be available under Alternative D. In sharp contrast to this, comparing the No Action/No Project to Alternative D in Table 3.3-1 indicates there will be a decrease in the number of annual passengers served in 2015 by domestic air carriers from 42 million annual passengers to 40 million annual passengers, with an increase in passengers served by smaller commuter planes. These assumptions do not appear to be supported, and a detailed explanation and justification of the reduction in trips provided by air carriers must be provided to ensure that the impacts of Alternative D are not understated.
5. Collateral Development Trip Cap Is Incorrect – Page 2-117 indicates there will be a cap associated with the LAX Northside Development to limit trips to a level comparable to the Westchester Southside Development shown with Alternatives A, B, and C. Page 2-117 indicates “The total development of the subject property shall not generate more than 3,152 project related outbound

vehicle trips in the a.m. peak hour and 3,040 project related outbound vehicle trips in the p.m. peak hour." With the LAX Northside Development including a business park with up to 4.5 million square feet of office, retail, and hotel space on 340 acres, it cannot possibly generate 3,152 outbound a.m. peak hour trips. Instead, a.m. peak hour trips will be predominately inbound as employees drive to the proposed business park. The collateral development must have an a.m. peak hour trip cap for inbound trips, not for the outbound trips which will be nominal in comparison.

6. Reduced Trip Cap for Collateral Development May Not Be Possible – Page 2-117 indicates "The original LAX Northside Development provided entitlements for 4.5 million square feet of development, subject to a limitation on the total number of daily vehicle trips (a 'trip cap.') Alternative D includes a proposed reduction in the existing trip cap included in the original LAX Northside Development." While the LAX Northside Development is proposed to occur on about 340 acres of airport owned land, it may not be possible to commit to a reduced trip cap as the LAX Northside Development has already been entitled at a much higher density that would have generated considerably more vehicle trips. Furthermore, the conversion from the approved daily trip cap associated with the larger entitled development to the proposed peak hour trip caps for the collateral development has not been documented in the Master Plan or in the Supplement. Supporting calculations must be provided to ensure the reductions of 50 percent in the a.m. peak hour and 57 percent in the p.m. peak hour claimed on Page 2-117 will be achieved.

LAX Master Plan Supplement Traffic Comments

The following concerns, omissions, and deficiencies relate to traffic impacts associated with Alternative D upon the City of El Segundo. These comments were developed during our detailed review of the traffic related portions of the Supplement as well as the S2b June 2003 Supplemental Off Airport Surface Transportation Technical Report prepared by Parsons Transportation Group.

1. Interim Year Analyses Are Required for Alternative D – Page 4-5 of the Supplement indicates that no interim year analysis in 2005 was prepared for Alternative D. The primary reason for this cited the major project features common to Alternatives A, B, and C that are not included in Alternative D. However, with the three separate phases shown on Pages 3-50 through 3-56 of the Supplement, analyses must be conducted for each phase of Alternative D so the timely mitigation of associated traffic impacts will occur.

Each phase of Alternative D contains major components that will significantly alter traffic patterns and impacts. As examples, the 12,400 space employee parking structure will consolidate many scattered employee parking lots into one facility, increasing employee vehicle trips along the south side of LAX.

Ms. Christy H. Taylor
LAX Master Plan Alternative D Traffic Comments
October 28, 2003

Construction of the Intermodal Transportation Center with its replacement parking for the structures in the Central Terminal Area will shift traffic volumes and associated impacts to areas southeast of LAX. The Ground Transportation Center will shift traffic volumes and impacts to areas northeast of LAX. The traffic impacts after completion of each phase must be identified, together with the timely implementation of necessary mitigation measures.

While the Supplement does examine traffic impacts in 2008 during the peak of construction activity for Alternative D, this is insufficient given the three major components in Alternative D. Demolition of the parking structures in the Central Terminal Area and construction of the Intermodal Transportation Center and Ground Transportation Center will each cause significant vehicle traffic shifts that require timely implementation of mitigation measures. Further study is required to ensure this occurs and impacts are mitigated.

2. Inappropriate Baseline Traffic Counts Have Been Used – Page 4-218 of the Supplement indicates the airport peak hour traffic data were collected in the Central Terminal Area in August 1996 while the traffic count data for morning and evening commuter peak hours were collected in March 1997. Additional traffic counts were also made in the Central Terminal Area on three Fridays in August 2000 for the airport peak hour and on two Fridays in March 2000 for the a.m. and p.m. peak commuter traffic hours. Table S4.3.1-1 shows the comparison in trips between 1997 and 2000 in the Central Terminal Area. The 1.8 percent increase per year in the airport peak hour trips, 7.2 percent over the four years, is significant. Similarly, the 0.6 percent increase per year in the p.m. peak hour trips, 1.9 percent over 3 years, is also significant.

We disagree with the Supplement statement that “The results of the surveys completed for Year 2000 conditions showed no material or consistent change in traffic growth or reduction in on airport traffic since August 1996/March 1997.” The increases of 1.8 percent per year for the airport peak hour trips as well as the increases of 0.6 percent per year in the p.m. peak hour trips are both significant. Annual growth rate adjustments must be made to the future baseline background traffic to properly reflect the increasing peak hour traffic volumes associated with activities at LAX.

Our July 16, 2001 comments on the LAX Draft EIS/EIR for Alternatives A, B, and C, questioned the use of summer airport peak hour traffic volumes to evaluate a worst case scenario. We believe traffic during holiday periods, and in particular Thanksgiving and Christmas, may be significantly higher than the traffic levels during August or during March. The Supplement must provide the factual basis for relying on August and March traffic volumes for the airport peak hour and for the a.m. and p.m. peak hours respectively instead of higher holiday traffic volumes.

Ms. Christy H. Taylor
LAX Master Plan Alternative D Traffic Comments
October 28, 2003

Regarding baseline traffic volumes at intersections, Page 4-244 of the Supplement indicates data was provided by LADOT for 38 intersections near the airport, with traffic counts made in 1994, 1995, and 1997. The Supplement indicates traffic counts were made at the intersections on June 1, 2001, and "A comparison of the data showed that the average annual growth for the combined intersections was approximately 1.5 percent and 1.0 percent per year for the a.m. and p.m. peak hours respectively." Page 2-244 concludes "It is a small growth rate and indicates that 1996 conditions are still applicable as an environmental baseline condition."

No data has been provided in the Supplement or in Technical Report S-2b to support the conclusion that 1996 conditions are the appropriate baseline. The 38 intersections counted and compared represent less than half of the 85 intersections evaluated in the Supplement. Each of these 38 intersections are in the City of Los Angeles, but traffic volume trends at these intersections may not be representative of traffic growth in the other adjacent jurisdictions such as the City of El Segundo or the County of Los Angeles. Further, there was no comparison of traffic volume increases on any of the 30 street segments or at any of the 39 ramps or four freeway segments included in Technical Report S-2b. Without further comparison, the Supplement cannot conclude "that 1996 conditions are still applicable as an environmental baseline condition."

According to counts provided by the City of El Segundo, traffic volumes on arterial segments have increased significantly between 1998 and 2003, particularly on Sepulveda Boulevard. The 1998 daily traffic volumes south of Imperial Highway of 64,700 increased to 69,800 in 2003, nearly 8 percent over the five years. South of El Segundo Boulevard, the 1998 daily traffic volumes of 57,500 increased to 61,800 in 2003, also nearly 8 percent over the five years. These increases in traffic on Sepulveda Boulevard require the Supplement to compare traffic growth in the area and to thoroughly document "1996 conditions are still applicable as an environmental baseline condition."

The preferred practice in conducting environmental analyses requires evaluation of reasonably expected worse case conditions. There was no attempt to factor or update the old traffic counts to include seasonal adjustments reflecting higher holiday traffic volumes. The Supplement does not indicate if an annual growth rate was applied or what percentage annual growth rate was used to establish conditions in 2015. The use of outdated baseline traffic counts results in an inaccurate analysis of existing conditions and traffic impacts of Alternative D. New traffic counts must be made at all intersections studied. The calculations and subsequent analysis must also be redone as outlined in this report to properly analyze the traffic impacts.

3. Caltrans Traffic Study Guidelines Were Not Followed - The traffic analysis of Alternative D should have been prepared in accordance with the California

Department of Transportation's "Guide for the Preparation of Traffic Impact Studies." A number of freeway ramps as well as mainline sections of the adjacent I-405 and I-105 Freeways will be significantly impacted by Alternative D. Adding even a single trip to freeway segments operating at Level of Service E or F requires detailed study according to these Guidelines.

4. Primary Mitigation Measures May Not Be Built Together As One Project - The primary mitigation of traffic impacts associated with Alternative D relies heavily on both a new interchange with I-405 at Lennox Boulevard as well as new connector ramps to and from I-105. These significant improvements have been analyzed together in the Supplement as a single project rather than as two separate improvements. There is no indication in the Supplement that the State will support either or both of these projects. The traffic impacts of Alternative D must be evaluated separately with only the Lennox Boulevard Interchange in place as mitigation and with only the I-105 connectors in place as mitigation. This additional evaluation is necessary given the complex nature of these improvements and the many uncertainties that will be faced in the lengthy State process. This will also complement the analyses already performed in the Supplement for future conditions without both of these significant improvements. The Supplement must also address the cost, financing, scheduling, and responsibility for implementation of these mitigation measures as required in the Caltrans Traffic Study Guidelines.
5. Public Parking Provided in Year 2015 May Be Insufficient - Table S4.3.1-7 on Page 4-235 of the Supplement indicates Alternative D creates a daily demand of 35,636 public parking spaces, and that this daily demand will exceed the planned public parking capacity by 634 parking spaces. The Supplement should indicate this is a significant environmental impact, but it does not recommend any measures to mitigate impacts of inadequate public parking.

Table S4.3.1-7 also indicates that the daily public parking demand for each of the four build alternatives (A, B, C, and D) is precisely identical at 35,636 public parking spaces. At the same time, the number of originating daily passengers ranges from 95,026 for Alternative D to 108,355 for Alternatives A and B. This significant range of over 13,000 originating daily passengers cannot possibly produce precisely identical public parking demands.

It is also unclear why the No Action/No Project alternative serving 87,280 originating daily passengers, 8,000 per day less than Alternative D, would require 1,000 more public parking spaces than any of the other four alternatives. Page 4-235 indicates "There would be fewer connecting passengers in Alternative D than in the No Action/No Project Alternative" but this contradicts the significant increase in commuter flights shown in Table S3-3 (160,400 annual in 2015 for the No Action/No Project vs. 182,800 annual in 2015 for Alternative D.)

Ms. Christy H. Taylor
LAX Master Plan Alternative D Traffic Comments
October 28, 2003

More originating daily passengers for Alternative D will either produce more vehicle trips or more significant transit impacts, neither of which has been identified or adequately addressed in the Supplement. These various discrepancies associated with public parking spaces, vehicle trips, and transit impacts must be corrected and appropriate mitigation measures developed.

6. Excessive Employee Parking Is Being Proposed – Page 4-235 indicates a new 12,400 stall garage would be built on the west side of the airport and there are also 1,200 employee parking spaces available in the existing Century Cargo Complex. In combination, 13,600 employee parking spaces are proposed with Alternative D. However, the demand for employee parking is shown as 12,400 parking spaces in Table S4.3.1-8 on Page 4-236 under each of the four build alternatives as well as under the No Action/No Project alternative. Providing an additional 1,200 employee parking spaces above what is needed to accommodate the forecast employee parking demand in a new, expensive parking structure is unnecessary and a further indication that the Master Plan contemplates greater growth than is being disclosed under Alternative D. The Master Plan and Supplement must be revised to reduce employee parking to match forecast demand and provide additional public parking to address the forecast shortage discussed above.

7. Discrepancies in the Peak Hour Trip Forecasts Must Be Corrected – Table S4.3.2-1 on Page 4-251 provides estimates of peak hour trips in 2015 for the No Action/No Project alternative but the numbers in this table do not match the sum of the inbound and outbound trips presented earlier in Table S4.3.1-3 on Page 4-227 as follows:

No Action/No Project Peak Hour Trips in 2015

Peak Hour	Table S4.3.1-3	Table S4.3.2-1
a.m.	13,096	13,105
Airport	17,602	18,296
p.m.	14,314	14,270

Similar discrepancies occur for peak hour trips in 2015 forecast for Alternative D between Table S4.3.2-1 on Page 4-252 and the sum of the inbound and outbound trips shown in Table S4.3.1-4 on Page 4-228 as follows:

Alternative D Peak Hour Trips in 2015

Peak Hour	Table S4.3.1-4	Table S4.3.2-1
a.m.	11,447	11,891
Airport	20,594	21,107
p.m.	12,602	13,072

These discrepancies in peak hour trips indicate that the analysis of the Supplement may be fundamentally flawed. The data must be reviewed and these discrepancies reconciled and corrected.

8. Trip Cap for LAX Northside Collateral Development Is Incorrect – Page 3-50 of the Supplement indicates the LAX Northside Development “would include a mix of office park, hotel, retail/restaurant, and research/development business park uses.” When describing the proposed trip cap associated with the LAX Northside Development, Page 3-50 of the Supplement indicates “The total development of the subject property shall not generate more than 3,152 project related outbound trips in the a.m. peak hour.”

The “outbound” trip cap is nonsensical. It is not clear whether any meaningful cap is included in Alternative D. Table S8 on Page 22 of Technical Report S2-b and Table S4.3.2-1 on Page 4-252 of the Supplement indicate the collateral trips associated with Alternative D, LAX Northside, would total 4,134 in the a.m. peak hour with the trip cap in place. The table does not specify the direction of these trips. However, the predominance of a.m. trips associated with the uses proposed in LAX Northside would be inbound in the a.m. peak hour, not outbound. Application of a very high a.m. peak hour outbound trip cap is meaningless. Further, the trip distribution in the Supplement analysis must correlate with the appropriate number of inbound and outbound peak hour trips associated with the LAX Northside Development.

9. Reduced Trip Cap for Collateral Development May Not Be Possible – Page 3-50 of the Supplement indicates “The original LAX Northside Development provided entitlements for 4.5 million square feet of development, subject to a limitation on the total number of daily vehicle trips (a ‘trip cap.’) Alternative D includes a proposed reduction in the existing trip cap included in the original LAX Northside Development.” While the LAX Northside Development is proposed to occur on about 340 acres of airport owned land, it may not be possible to commit to a reduced trip cap as the LAX Northside Development has already been entitled at a much higher density that would have generated considerably more vehicle trips. Furthermore, the conversion from the approved daily trip cap associated with the larger entitled development to the proposed peak hour trip caps for the collateral development has not been documented in the Supplement. Supporting calculations must be provided to ensure the reductions of 50 percent in the a.m. peak hour and 57 percent in the p.m. peak hour claimed on Page 3-50 of the Supplement will be achieved.
10. Inconsistencies in Alternative D Construction Schedule Must Be Corrected – The Supplement indicates substantial shifts in airport traffic patterns will occur as the major components of Alternative D are constructed. Page 4-264 indicates “When the ITC comes on line, there is expected to be a substantial shift in airport traffic patterns, as much of the CTA traffic shifts to the ITC. This

traffic shift would result in significant impacts to various roadway intersections and ramps. As much as possible, it is important that the mitigation of these impacts be in place prior to opening the ITC, so that the corresponding traffic shifts can be adequately accommodated." We agree. However, several contradictions to this idealized construction schedule appear in Table S3-15 including the following :

- a) Intermodal Transportation Center Construction – This project is shown as a design build project beginning in the 4th quarter of 2003, completion of construction at the end of the 4th quarter in 2005, and testing in the 1st quarter of 2006.
- b) Central Terminal Area Parking Structure Demolition – This project is scheduled to begin in the 4th quarter of 2005 and to be completed at the end of the second quarter of 2006. If this schedule is followed, there would be no short term parking in the Central Terminal Area or at the Intermodal Transportation Center for at least six months, creating chaos.
- c) Off Site Roadway Improvements – These projects are scheduled to begin during the 1st quarter of 2006, with completion at the end of the 2nd quarter of 2008. If this schedule is followed, there would be no mitigation measures in place at impacted intersections for over two years following completion and opening of the Intermodal Transportation Center at the end of the 1st quarter of 2006.

Construction of the off site roadway improvements, which are assumed in the analysis in the Supplement, must be accelerated so they are in place prior to opening of the Intermodal Transportation Center, not more than two years after as shown in the project schedule. The construction of the major components of Alternative D must also be rescheduled to retain short term public parking in the Central Terminal Area until the Intermodal Transportation Center is ready for use. There will be significant impacts if the construction schedule is not modified to address these concerns.

11. Construction Worker and Truck Trip Estimates Are Inconsistent – Table 4.3.2-9 provides estimates of construction employee and truck traffic in 2008, the peak year of construction activity according to the Supplement. This table indicates there will be 5,953 daily construction employee trips and 5,326 passenger car equivalent truck trips, but the sum of these trips (11,279) does not equal the total construction trips of 11,273 shown in the table.

Page 4-544 of the Supplement provides a significantly higher estimate of construction workers during the peak construction years in 2007 and 2008, indicating "the workforce would equate to 5,992 personnel." Assuming that each construction employee would drive alone to and from LAX, this

workforce would generate 11,984 daily construction employee trips. This is a huge difference, more than double the number of employee trips shown in Table S4.3.2-9 which was used as the basis for analysis of construction trips throughout the Supplement. The number of employees in the workforce and the subsequent evaluation of traffic impacts in Section 4.3.2 of the Supplement were based on less than 50 percent of the workforce estimated in Section 4.20 on Page 4-544, significantly understating the traffic impacts associated with construction employee trips. These significant and unexplained discrepancies must be addressed and resolved, and appropriate mitigation measures for construction traffic developed.

When describing the highest construction workforce and truck demand in 2008, Page 4-556 of the Supplement provides yet a different estimate by indicating "During the peak construction year, there will be an average daily employment of 5,125 and an average of 1,064 truck trips per day." Assuming that each construction employee would drive alone to and from LAX, this workforce would generate 10,250 daily construction employee trips. This is another huge discrepancy, nearly double the number of employee trips shown in Table S4.3.2-9 which was used as the basis for analysis of construction trips throughout the Supplement. The number of employees in the workforce and the subsequent evaluation of traffic impacts in Section 4.3.2 of the Supplement were based on 60 percent of the workforce estimated on Page 4-556, significantly understating the traffic impacts associated with construction employee trips. These discrepancies must be addressed and resolved, and appropriate mitigation measures developed.

The Supplement fails to adequately evaluate the traffic impacts associated with construction employees and truck traffic. As noted above, Table S4.3.2-9 is based upon the lowest estimate of the number of construction employees found in the Supplement, a number that is less than half of that disclosed in Chapter 4.20 of the Supplement. Thus, the traffic analysis shows less than half of the traffic that should have been analyzed, and must be redone using the corrected construction employee and truck trip data.

12. Peak Hours at Intersections and Central Terminal Area May Be Different - Page 4-269 indicates "no construction related trips between LAX construction sites and off airport locations occur during the peak commute hours of 8:00 to 9:00 a.m. and 5:00 to 6:00 p.m. Also, very few vehicle trips occur during the airport peak hour of 11:00 a.m. to noon."

The peak hours used throughout the Supplement were defined by reviewing data at the Central Terminal Area for LAX operations. According to Page 4-556 and footnotes in Table S4.3.1-1 on Page 4-221, the morning peak hour occurs from 8:00 to 9:00 a.m., the airport peak hour occurs from 11:00 a.m. to 12:00 noon, and the afternoon peak hour occurs from 5:00 to 6:00 p.m.

However, these hours may not actually correspond to the highest 60 minutes of traffic during the morning and the afternoon peak periods at the various intersections and freeway segments studied. Intersections experience their highest peak hour volumes during the four consecutive 15 minute periods such as from 7:15 to 8:15 a.m. rather than corresponding exactly to even hours such as from 8:00 to 9:00 a.m. The Supplement must document the highest 60 minute period in both the morning and evening peak periods at each of the intersections and roadway segments and then analyze the traffic impacts of Alternative D in these true peak hours.

13. Analysis of Construction Related Traffic During Additional High Volume Hours Must Also Be Made - Both of the statements on Page 4-269 regarding no construction related trips during peak hours are also misleading for the additional reason that the morning and afternoon peak traffic periods extend well beyond a single hour. Traffic at intersections and on various freeway segments near LAX approaches or exceeds capacity for several hours in the morning and for the majority of the afternoon and evening hours, and the traffic impacts associated with Alternative D upon these facilities must be analyzed and mitigated as discussed below.

Table S4.3.2-10 provides a comparison of hourly traffic volumes on various freeway and arterial roadway segments, both without construction traffic and then with construction traffic added. However, this table fails to assess the freeway and arterial roadway segment capacities and the levels of service associated with these construction traffic increases. The Supplement must properly evaluate the impacts of construction related traffic by direction on the freeway and arterial street segments shown in Table S4.3.2-10 as well as upon freeway segments adjacent to LAX.

As one example, Table S4.3.2-10 fails to properly quantify the amount of construction traffic that will impact Sepulveda Boulevard south of El Segundo Boulevard. Between 11:00 a.m. and 12:00 noon, this table indicates there will be 1,016 airport related trips in 2008 on this roadway segment without any construction traffic. Between 11:00 a.m. and 12:00 noon, this table also indicates there will be exactly 1,016 airport related trips in 2008 on this roadway segment with construction traffic. However, Table S4.3.2-9 indicates there will be 975 passenger car equivalent construction trips in 2008 between 11:00 a.m. and 12:00 noon. Airport related traffic forecast on Sepulveda Boulevard south of El Segundo Boulevard cannot possibly be identical with and without construction traffic between 11:00 a.m. and 12:00 noon with 975 trips related to construction forecast to occur during this hour.

As another example, the eight mixed flow lanes on the mainline of I-405 south of Rosecrans Avenue have a total capacity of 16,000 vehicles per hour. Using the volumes shown in Table S4.3.2-10, the freeway mainline operates at

Ms. Christy H. Taylor
LAX Master Plan Alternative D Traffic Comments
October 28, 2003

Level of Service E between 3:00 and 4:00 p.m. without any LAX construction traffic. Without construction traffic, this table indicates there will be 5,406 airport trips on I-405 south of Rosecrans Avenue during this hour. With construction traffic, this table indicates there will be 6,162 airport trips on I-405 south of Rosecrans Avenue during this hour. Subtracting the airport traffic without construction vehicles from the airport traffic with construction traffic indicates 756 LAX construction related vehicles will use I-405 south of Rosecrans Avenue between 3:00 and 4:00 p.m. These construction vehicles bring the total volume between 3:00 and 4:00 p.m. on I-405 south of Rosecrans Avenue to 16,459 as shown in Table S4.3.2-10. This exceeds the 16,000 vehicles per hour mainline freeway capacity and causes the level of service to degrade from LOS E to LOS F. This is a significant traffic impact which is not disclosed in the Supplement.

The Supplement's failure to disclose this significant adverse effect on I-405 south of Rosecrans Avenue is a significant flaw. The Supplement must be substantially revised to reflect the correct number of construction workers, disclose their associated traffic impacts and provide measures to mitigate construction traffic impacts upon intersections, street segments, and freeway facilities that will be impacted during high traffic hours.

14. The Full Impacts of Construction Traffic Are Not Fully Disclosed and Require Additional Mitigation at Intersections - According to Table S4.3.2-8, eight of the nine intersections studied in the City of El Segundo will be impacted by Alternative D in 2008 prior to mitigation. According to this table, significant traffic impacts will occur as follows:

- ❖ Aviation Boulevard at El Segundo Boulevard (LOS E in all peak hours)
- ❖ Aviation Boulevard at Imperial Highway (LOS E in the a.m. peak hour)
- ❖ Aviation Boulevard at Rosecrans Avenue (LOS F in the airport peak hour)
- ❖ Imperial Highway at Douglas Street (LOS C in the p.m. peak hour)
- ❖ Sepulveda Boulevard at El Segundo Boulevard (LOS F in the a.m. and LOS E in the airport peak hours)
- ❖ Sepulveda Boulevard at Imperial Highway (LOS D in the a.m. and LOS F in the airport and p.m. peak hours)
- ❖ Sepulveda Boulevard at Mariposa Avenue (LOS D in the a.m. and LOS F in the airport and p.m. peak hours)
- ❖ Sepulveda Boulevard at Rosecrans Avenue (LOS F in the a.m. and p.m. peak hours)

However, Table S4.3.2-8 does not adequately identify conditions that will occur during the airport peak hour in 2008 as it omits the additional impacts of construction traffic upon these intersections. Pages 4-264 and 4-265 indicate the procedures used to calculate intersection capacity "do not account for construction traffic for the three primary peak hours" and "the project would be

managed to ensure that there would not be any notable construction related traffic generated by the project during those critical hours." For the airport peak hour from 11:00 a.m. to 12 noon, these statements directly contradict the Summary of 2008 Airport Construction Trip Generation in Table S4.3.2-9 on Page 4-270 which shows 975 passenger car equivalents for truck trips between 11:00 a.m. and 12:00 noon. The analysis of the airport peak hour in the Supplement must be modified to include these passenger car equivalent truck trips. The volume/capacity ratios and LOS shown in Table S4.3.2-8 must be corrected and further measures must be developed to mitigate these additional construction traffic impacts in the airport peak hour.

It is extremely unreasonable to assume there will be no construction trips occurring in 2008 between 8:00 a.m. and 11:00 a.m. as well as between 5:00 and 7:00 p.m. as has been shown in Table S4.3.2-9. Certainly, some of the 11,273 daily construction trips that are forecast in 2008 in this table will occur during the hours when absolutely no activity has been shown, particularly during the a.m. and p.m. peak hours. The Supplement's statement that "the project would be managed to ensure that there would not be any notable construction related traffic generated by the project during those critical hours" is unsupported by any definitive plans or measures to ensure that there will be zero construction traffic during the a.m. and p.m. peak hours. Table S4.3.2-9 must be revised to properly forecast construction trips. The volume/capacity ratios and LOS shown in Table S4.3.2-8 must be corrected and further measures must be developed to mitigate these additional construction traffic impacts in the a.m. and p.m. peak hours.

15. Century Boulevard Lane Closures Are Not Adequately Analyzed – Page 4-547 of the Supplement indicates lanes on Century Boulevard will be closed as a result of the construction of various components of Alternative D as follows: "The traffic to and from the airport may be rerouted to southbound Sepulveda Boulevard for I-105 and Imperial Highway access, and to northbound Sepulveda Boulevard on to La Tijera Boulevard for I-405 access. These alternative routes may stay in effect for over two years." The Supplement has not assessed or properly evaluated the traffic impacts of the Century Boulevard long term lane closures on Sepulveda Boulevard south or north of LAX. Further study and disclosure of the impacts is required, together with the formulation and adoption of mitigation measures.

16. Construction Staging Area Traffic Impacts Are Not Adequately Analyzed – Pages 4-548 and 4-549 indicate six construction staging areas have been identified. These include Staging Area 4 at the west end of the south runways north of Imperial Highway and east of Pershing Drive and Staging Area 5 at the west end of the south runways just east of Staging Area 4. The Supplement fails to provide any details regarding how or when the various staging areas may be used. Important issues relating to each staging area

including when it will be used, how long it will be used, where access will be provided, and how many trips will occur, must be addressed and disclosed. The impacts must be analyzed and disclosed, and mitigation measures must be formulated and included in the Supplement.

17. Improved Mitigation for Construction Traffic Must Be Formulated– Page 4-568 of the Supplement indicates “Although surface transportation commitments would reduce the impacts to on and off airport transportation facilities during construction, these impacts would remain significant and temporarily unavoidable.” As pointed out in this letter, there are many inconsistencies and errors in the estimates of construction traffic shown in the Supplement. The subsequent analysis based upon only a fraction of the projected construction traffic is inadequate, and the resulting traffic impacts have been grossly understated. These errors and inconsistencies must be rectified and appropriate mitigation measures must be developed and adopted for Alternative D.

18. Lennox Interchange and I-105 Connectors Are Not Adequately Analyzed - The Lennox Boulevard interchange with I-405 as well as the new connector ramps to and from the east on I-105 are very important components of the overall mitigation for Alternative D. Page 36 of Technical Report S2-b indicates “There are four on ramps to southbound I-405 and four off ramps from southbound I-405. One or two of these on ramps and up to two of these off ramps may need to be eliminated. Other ramps may be realigned” with the proposed mitigation. Closing of existing ramps must be evaluated in much more detail to assess whether the ramps remaining open such as at El Segundo Boulevard would become overloaded with diverted traffic associated with the proposed mitigation, and the project designed to avoid such impacts. The total of 5,750 CMP credits shown on Page 53 of Technical Report S-2b, 1,150 for each of the five new freeway ramps, must also be adjusted to reflect the final net change in on and off ramps.

The Supplement and Technical Report S-2b do not adequately address the role of the State Department of Transportation in the proposed Lennox Boulevard Interchange with I-405 and in the proposed eastbound I-105 connectors. Caltrans must review and approve all changes involving the I-405 and I-105 Freeways. These two significant mitigation measures must also be evaluated separately and independently rather than together as a single project as has been done in the Supplement. While alternate mitigation to both projects together has been developed, the Supplement must also develop alternate mitigation for the Lennox Boulevard Interchange and for the I-105 eastbound connectors separately.

19. Traffic Impacts to Freeway Mainlines Not Adequately Analyzed or Mitigated – Page 4-253 describes “poor traffic conditions that already exist on the I-405

Ms. Christy H. Taylor
LAX Master Plan Alternative D Traffic Comments
October 28, 2003

and I-105 mainlines." To address this critical problem, Page 4-254 of the Supplement indicates "It is important that Alternative D include a mitigation strategy that would help to alleviate this issue. Effective methods of encouraging airport traffic to stay on the freeway rather than off load would include provision of direct and non stop access ramps to and from I-405 and I-105..... Analysis shows that these two important mitigation components would be effective in encouraging airport traffic to stay on the freeway system and avoid off loading onto surface streets."

As indicated previously, the proposed mitigation involving the Lennox Boulevard interchange at I-405 together with the new connector ramps to and from the east on I-105 are important components of the overall mitigation for Alternative D. However, without significant improvement to both the I-405 and I-105 mainlines, airport traffic will still divert off both freeways onto surface streets upstream of LAX, even with the new interchange and the connectors.

Existing traffic volumes during the a.m., Airport, and p.m. peak hours as well as during most of the afternoon already approach capacity on both I-405 and on I-105. Various tables such as the Levels of Service for Freeway Mainline Segments in Attachment C to Technical Report S-2b show traffic forecasts exceeding the mainline freeway capacity. These volume projections indicate the demand to use the freeway but this is a theoretical number because these volumes exceed the actual capacity of the freeway segments. When the number of vehicles exceeds the mainline freeway capacity, vehicles will either divert to surface streets, causing additional adverse impacts on those streets, or they will be severely delayed, significantly extending peak hours.

I-405 south of Rosecrans Avenue provides four through lanes and one HOV lane in each direction with a corresponding directional capacity of 10,000 vehicles per hour. Unfortunately, a comparison of total freeway directional demand on I-405 cannot be made as the various tables in Attachment C for 2015 contain numerous errors regarding projections for the HOV lanes. (E.g., HOV volumes for 2015, shown to be only half of the 2008 HOV projections, must be corrected.)

Comparing the traffic volume forecasts in the four through mainline lanes with their associated capacity of 8,000 vehicles per hour indicates significantly more demand than these lanes can actually accommodate. According to the table in Attachment C for I-405 south of Rosecrans Avenue in 2008, the northbound a.m. peak hour demand will be 8,698 vehicles, 698 more than can be served on the mainline. During the Airport peak hour, the northbound demand will be 8,953 vehicles, 953 more than can be served. During the Airport peak hour, the southbound demand will be 8,408 vehicles, 408 more than can be served. During the p.m. peak hour, the southbound demand will be 9,271 vehicles, 1,271 more than can be served. To retain the traffic on the

Ms. Christy H. Taylor
LAX Master Plan Alternative D Traffic Comments
October 28, 2003

freeway, mainline improvements are needed to accommodate the number of vehicles exceeding the current freeway capacity. LAWA must pay its "fair share" of the required freeway widening.

Conditions in 2015 on the mainline of I-405 south of Rosecrans Avenue will be worse than those in 2008. According to the table in Attachment C for I-405 with the Lennox Boulevard Interchange, the northbound a.m. peak hour demand will be 9,054 vehicles, 1,054 more than can be served. During the Airport peak hour, the northbound demand will be 9,973 vehicles, 1,973 more than can be served. During the Airport peak hour, the southbound demand will be 9,668 vehicles, 1,668 more vehicles than can be served. During the p.m. peak hour, the northbound demand will be 8,632 vehicles, 632 more than can be served. During the Airport peak hour, the southbound demand will be 10,027 vehicles, 2,027 more vehicles than can be served. Again, in order to retain on I-405 the vehicles exceeding the freeway capacity, mainline improvements are required, and LAWA must pay its "fair share" of the required freeway widening.

A significant portion of the evaluation of traffic impacts of freeway mainlines contained in the Supplement in Table S4.3.2-5 includes remote freeway facilities far removed from LAX such as I-5 and I-405 over 25 miles north of LAX in the San Fernando Valley. The Supplement must examine the Alternative D traffic impacts on the I-405 and I-105 mainline freeway segments in the vicinity of LAX, where the impacts will be obvious and severe, in far more detail. This analysis will require special attention to the I-105 as freeway segments at I-405, Prairie Avenue, at Crenshaw Boulevard, and at I-110 provide only three through lanes and one HOV lane in each direction. These constrictions act as bottlenecks along I-105, and provide significantly less capacity than the wider four through lane and one HOV lane segment east of Crenshaw Boulevard mentioned in the Supplement. The traffic impacts of Alternative D on the constricted sections of I-105 must be evaluated and properly analyzed, with measures developed and added to the Supplement as necessary to mitigate these traffic impacts and avoid off loading of excess traffic volumes onto local surface streets.

The proposed freeway mainline mitigation shown in Attachment G to Technical Report S-2b includes only three improvement projects to freeway mainlines. All are located on I-405, with one at Santa Fe Avenue near I-710 in the City of Long Beach, one east of I-110 in the City of Carson, and one north of Inglewood Avenue in the City of Redondo Beach. No details whatsoever are provided regarding the scope or the costs of these proposed "future freeway improvements." No back up calculations have been provided to verify the "fair share" of proposed Alternative D participation of 7.7 percent, 10.0 percent, 75.0 percent, respectively, in these three projects. These flaws in the

Ms. Christy H. Taylor
LAX Master Plan Alternative D Traffic Comments
October 28, 2003

Supplement must be remedied in order to provide full disclosure of traffic impacts and potential mitigation.

20. Erroneous Calculations and Flawed Mitigation Measures For City of El Segundo Intersections Must Be Corrected – Each of the capacity calculations for intersections in the City of El Segundo in Attachment I to the S-2b Supplemental Off Airport Transportation Technical Report has been reviewed. These calculations contain numerous errors which have then been carried throughout Technical Report S-2b as well as in the Supplement. Each of the following comments must be addressed by correcting the intersection capacity calculations and modifying the recommended mitigation measures appropriately as follows:

a) Aviation Boulevard and El Segundo Boulevard

- i) Los Angeles County Widening Project Benefits Alternative D – The capacity calculations assume a Los Angeles County project will add a third through lane in each direction on Aviation Boulevard prior to 2008. These additional lanes result in significantly improved capacity and level of service over what will actually occur if the County project is not constructed by 2008. Alternative D obtains a significant increase in capacity at this intersection from a project being implemented by another jurisdiction. LAWA should contribute its “fair share” to the cost of the County improvement project as mitigation of Alternative D.
- ii) Southbound Aviation Boulevard Restriping Is Not Included – The a.m. peak hour calculations for 2015 with the Lennox Boulevard Interchange match the recommended mitigation. However, for both the airport and p.m. peak hours, calculations do not reflect restriping southbound Aviation Boulevard to two left turn lanes, 2 through lanes, and 1 through/right lane as recommended in the mitigation of impacts at this intersection.
- iii) ATSAC/ATCS System Is Now Being Designed – Calculations in 2015 include capacity benefits with implementation of ATSAC/ATCS signal control. The County of Los Angeles is currently designing an ITS traffic signal system improvement project throughout the City of El Segundo. The Supplement incorrectly credits Alternative D for traffic signal system mitigation that will already be in place long before 2015. LAWA should contribute its “fair share” to the cost of the County improvement project as mitigation of Alternative D. The Supplement must also develop other measures to mitigate the traffic impacts of Alternative D at this intersection.

iv) Mitigation Measures Are Incorrect – Dual left turn lanes for only southbound traffic have been recommended as mitigation in 2015. Dual left turn lanes are generally beneficial to intersection capacity when left turning traffic volumes exceed 300 in a peak hour. At this intersection, southbound left turn volumes are considerably less than this accepted threshold in all scenarios. While northbound left turn volumes exceed this threshold significantly in the Airport peak hour, northbound dual left turn lanes were not recommended as mitigation. In addition, dual left turn lanes in only one direction on Aviation Boulevard would create an adverse and potentially unsafe offset for through traffic as it passes through the intersection. These mitigation measures must be reviewed and redesigned to ensure that they serve their purpose without endangering public safety.

b) Aviation Boulevard and Imperial Highway

i) Southbound Aviation Boulevard Through Lanes Are Incorrect – Currently there is only one dedicated southbound through lane. All calculations for 2008 and 2015 include a second dedicated through lane but the project that will provide this second southbound through lane has not been identified.

ii) Southbound Aviation Boulevard Right Turn Lanes Are Incorrect – Currently there is a dedicated southbound right turn lane as well as a southbound shared through/right turn lane. A southbound right turn arrow is also displayed by the traffic signal. All calculations for 2008 and 2015 include these lanes but do not correctly calculate the capacity of the shared through/right turn lane green arrow. The calculations must be adjusted to reflect blockage of the shared lane by a through motorist while the right turn green arrow is displayed.

iii) Arbitrary Volume Adjustments Were Made For 2015 – Calculations for the a.m. peak hour in 2015 for unmitigated and for mitigated conditions without the Lennox Boulevard Interchange include an increase of 300 northbound through vehicles and a decrease of 100 southbound left turn vehicles for the "Project." Many adjustments are made during the Airport peak hour in 2015 for "Ambient" including 175 more northbound right turns, 200 more southbound left turns, 50 fewer southbound through vehicles, 200 more westbound right turns, 300 fewer eastbound left turns, 300 more eastbound through, and 100 fewer eastbound right turns. In the p.m. peak hour, these "Ambient" adjustments include 200 fewer northbound left turns and 200 more southbound left turns. The Supplement must provide technical support for each of these arbitrary "Project" and "Ambient" peak hour volume adjustments as well as the rationale for making adjustments in seven

Ms. Christy H. Taylor
LAX Master Plan Alternative D Traffic Comments
October 28, 2003

movements during the Airport peak hour and in only two movements in the a.m. and p.m. peak hours.

c) Aviation Boulevard and Rosecrans Avenue

- i) Hawthorne Widening of Aviation Boulevard Benefits Alternative D – The capacity calculations assume a City of Hawthorne project will add a second northbound left turn lane, a dedicated northbound right turn lane, a second southbound left turn lane, two additional southbound through lanes, and a dedicated southbound right turn lane prior to 2008. These additional lanes result in significantly improved capacity and level of service over what will actually occur if the City of Hawthorne project is not constructed by 2008. Alternative D obtains a significant increase in capacity at this intersection from a project being implemented by another jurisdiction. LAWA should contribute its “fair share” to the cost of these improvements as mitigation of Alternative D.
- ii) Hawthorne Widening of Rosecrans Avenue Benefits Alternative D – The capacity calculations assume a City of Hawthorne project will add an additional westbound through lane, a second eastbound left turn lane, and an additional eastbound through lane prior to 2008. These additional lanes result in significantly improved capacity and level of service over what will actually occur if the City of Hawthorne project is not constructed by 2008. Alternative D obtains a significant increase in capacity at this intersection from a project being implemented by another jurisdiction. LAWA should contribute its “fair share” to the cost of these improvements as mitigation of Alternative D.

d) Imperial Highway and Douglas Street

- i) Traffic Signal Phasing Is Incorrect – Douglas Street and the access into the cargo area at LAX operate on separate or split phases at this time and in the calculations for conditions in 2008. However, all calculations for 2015 incorrectly assume removal of the split phasing and show northbound and southbound traffic entering Imperial Highway simultaneously. The 2015 calculations are incorrect as the split phasing operation must be retained with the multiple and shared turning lanes for northbound and southbound traffic. These errors result in incorrect conclusions about levels of congestion at this intersection and the analysis for 2015 understates the impacts of Alternative D upon this intersection.
- ii) Arbitrary Volume Adjustments Were Made For 2015 – Calculations for the p.m. peak hour in 2015 for unmitigated and for mitigated conditions without the Lennox Boulevard Interchange include an increase of 200

northbound left turn vehicles for "Ambient." The Supplement must provide technical support for these arbitrary "Ambient" p.m. peak hour volume adjustments, as well as the rationale for making no adjustments during the a.m. and Airport peak hours.

- iii) 2015 Traffic Analysis Assumes Incorrect Mitigation Measures – Recommended mitigation involves elimination of the third eastbound through lane on Imperial Highway to create a northbound free right turn from Douglas Street. However, the Supplement's calculations for 2015 with the Lennox Boulevard Interchange in the a.m. peak hour still show three eastbound through lanes on Imperial Highway together with the northbound free right turn lane. In addition, each of the peak hour calculations for conditions in 2015 with the Lennox Boulevard Interchange incorrectly show a dual northbound free right turn whereas only a single northbound free right turn has been recommended. Each of these calculations must be corrected before the appropriate measures to mitigate this impacted intersection can be developed.
 - iv) Impacts on Bicycle Lane Must Be Analyzed - The impacts of the proposed free right turn lane upon the existing striped eastbound bicycle lane on Imperial Highway must be evaluated.
 - v) Further Analysis of Two Way Operation Is Required – Douglas Street and Nash Street presently operate as a one way couplet south of Imperial Highway. Nash Street now carries only southbound traffic and Douglas Street now carries only northbound traffic. The City of El Segundo is considering converting this one way couplet to two way traffic flow on both streets. In addition to correcting the analysis of the Imperial Highway/Douglas Street intersection to address the comments above, the Supplement should also analyze the traffic impacts of Alternative D upon this intersection if Douglas Street is converted to two way traffic. The Supplement should also analyze the traffic impacts of Alternative D at the Imperial Highway/Nash Street intersection if Nash Street is converted to two way traffic.
- e) Sepulveda Boulevard and El Segundo Boulevard
- i) Eastbound Lanes on El Segundo Boulevard Are Incorrect – All of the calculations for conditions in 2008 and 2015 incorrectly show one eastbound shared left turn/through lane on El Segundo Boulevard. This lane is a dedicated eastbound through lane and left turns cannot be legally made from this through lane.
 - ii) Split Phasing East/West Was Not Evaluated Correctly – Eastbound and westbound traffic on El Segundo Boulevard now operates on

separate, or split, phases. During the traffic signal cycle, all westbound traffic proceeds on El Segundo Boulevard, followed by all eastbound traffic during a separate traffic signal phase. However, all calculations for 2008 and 2015 incorrectly assume removal of the split phasing and show eastbound and westbound traffic entering Sepulveda Boulevard simultaneously. The 2008 and 2015 calculations are incorrect as the split phasing operation must be retained with the multiple and shared turning lanes for eastbound and westbound traffic. These errors result in incorrect conclusions about levels of congestion at this intersection and the analyses for 2008 and 2015 understate the impacts of Alternative D upon this intersection.

- iii) Arbitrary Volume Adjustments Were Made For 2015 – Calculations for the a.m. peak hour in 2015 for unmitigated and for mitigated conditions without the Lennox Boulevard Interchange include a decrease of 100 northbound through vehicles and an increase of 100 westbound right turn vehicles for the "Project." No other adjustments were made during either the Airport peak hour in 2015 or in the p.m. peak hour in 2015. The Supplement must provide technical support for both of these arbitrary "Project" a.m. peak hour volume adjustments as well as the rationale for making no adjustments in any of the movements during the Airport or p.m. peak hours.
 - iv) ATSAC/ATCS System Is Now Being Designed – Calculations in 2015 include capacity benefits with implementation of ATSAC/ATCS signal control. The County of Los Angeles is currently designing an ITS traffic signal system improvement project throughout the City of El Segundo. The Supplement incorrectly credits Alternative D for traffic signal system mitigation that will already be in place long before 2015. LAWA should contribute its "fair share" to the cost of the County improvement project as mitigation of Alternative D. The Supplement must also develop other measures to mitigate the traffic impacts of Alternative D at this intersection.
- f) Imperial Highway and Main Street
- i) Northbound Main Street Lanes Are Incorrect – Northbound right turns are controlled by a YIELD sign outside of the traffic signal operation. In the Supplement, the northbound right turns have been incorrectly analyzed as a part of the traffic signal operation in all calculations for conditions in 2008 and 2015.
 - ii) Driveway Opposite Main Street Was Excluded – There is an existing driveway serving LAX directly opposite Main Street on the north side of Imperial Highway. This driveway has been erroneously omitted from

the calculations of capacity at this intersection and no traffic volumes have been assigned in to or out of this existing driveway serving LAX.

- iii) Eastbound Imperial Highway Lanes Are Incorrect – The separate eastbound right turn lane is controlled by a STOP sign outside the traffic signal operation. In the Supplement, the eastbound right turns have been incorrectly analyzed as a part of the traffic signal operation in all calculations for conditions in 2008 and 2015. Peak hour queuing in the eastbound through lanes which now blocks access to this right turn lane should also be analyzed and measures developed to mitigate additional impacts of Alternative D upon this condition at this location.
- iv) Mitigation Measures Are Flawed and Inadequately Analyzed – Mitigation proposed in 2015 includes a second westbound left turn lane. Installation of this lane will require roadway widening and modification of the median to preserve the existing bicycle lane, not simple restriping as proposed. Secondly, a northbound right turn green arrow has been incorrectly proposed as mitigation when this movement is free and it now occurs outside the traffic signal operation. Thirdly, the calculations for mitigation in 2015 include ATSAC/ATSC benefits even though improvements at this intersection do not list or identify this as a mitigation measure. Finally, all mitigation at this intersection must be reevaluated to address traffic signal coordination with the existing traffic signal on Main Street at Imperial Avenue only 100 feet south of Imperial Highway.

g) Sepulveda Boulevard and Imperial Highway

- i) Arbitrary Volume Adjustments Were Made For 2015 – Calculations for the a.m. peak hour in 2015 for unmitigated and for mitigated conditions without the Lennox Boulevard Interchange include a decrease of 200 northbound right turn vehicles, a decrease of 300 southbound left turn vehicles, an increase of 150 southbound through vehicles, a decrease of 100 southbound right turn vehicles, and an increase of 175 westbound left turn vehicles for the "Project." Many adjustments were also made during the Airport peak hour in the 2015 unmitigated analysis for "Ambient" including 175 more southbound right turns, 175 fewer southbound through vehicles, 25 more westbound left turns, and 175 more westbound right turns. These same adjustments were also made during the Airport peak hour for alternate mitigation without the Lennox Boulevard Interchange and a deduction of 300 southbound right turns was made under "Related." In the p.m. peak hour, no adjustments were made. The Supplement must provide technical support for each of these arbitrary "Project," "Ambient," and "Related" peak hour volume adjustments as well as the rationale for making

adjustments in five movements during the a.m. and Airport peak hours and none during the p.m. peak hours.

- ii) MTA Mitigation Measures Are Not Properly Analyzed – For conditions in 2015 without the Lennox Boulevard Interchange, the Supplement indicates 15 vehicles must be reduced from the intersection in the Airport peak hour and 5 vehicles must be reduced from the intersection in the p.m. peak hour. For conditions in 2015 with the Lennox Boulevard Interchange, the Supplement indicates 330 vehicles must be reduced from the intersection in the “critical” peak hour but does not define which peak hour is “critical.” None of the calculations in the Appendix to S-2b show these reductions to support the effectiveness of the proposed mitigation. Further, there is absolutely no assurance or guarantee that providing funding to MTA for improved Rapid Bus or other transit services would actually mitigate Alternative D traffic impacts at the intersection of Sepulveda Boulevard and Imperial Highway. Reducing demand by 330 vehicles in the “critical” peak hour would require at least seven buses, and providing this as a mitigation measure is absurd.

h) Sepulveda Boulevard and Mariposa Avenue

- i) Arbitrary Volume Adjustments Were Made For 2015 – Calculations for the a.m. peak hour in 2015 for unmitigated conditions without the Lennox Boulevard Interchange include a decrease of 200 northbound through vehicles, an increase of 200 northbound right turn vehicles, and an increase of 325 southbound left turn vehicles for the “Project.” Calculations for the a.m. peak hour in 2015 for alternate mitigation conditions without the Lennox Boulevard Interchange also include a decrease of 200 northbound through vehicles, an increase of 200 northbound right turn vehicles, and an increase of 325 southbound left turn vehicles for “Ambient.” No other adjustments were made during either the Airport peak hour in 2015 or in the p.m. peak hour in 2015. The Supplement must provide technical support for both of these arbitrary “Project” and “Ambient” a.m. peak hour volume adjustments as well as the rationale for making no adjustments in any of the movements during the Airport or p.m. peak hours.
- ii) ATSAC/ATCS System Is Now Being Designed – Calculations in 2015 include capacity benefits with implementation of ATSAC/ATCS signal control. The County of Los Angeles is currently designing an ITS traffic signal system improvement project throughout the City of El Segundo. The Supplement incorrectly credits Alternative D for traffic signal system mitigation that will already be in place long before 2015. LAWA should contribute its “fair share” to the cost of the County improvement

project as mitigation of Alternative D. The Supplement must also develop other measures to mitigate the traffic impacts of Alternative D at this intersection.

iii) MTA Mitigation Measures Are Not Properly Analyzed – For 2015 conditions without the Lennox Boulevard Interchange, the Supplement indicates 76 vehicles must be reduced from the intersection in the a.m. peak hour. For conditions in 2015 with the Lennox Boulevard Interchange, the Supplement indicates 52 vehicles must be reduced from the intersection in the a.m. peak hour. None of the calculations in the Appendix to S-2b show these reductions to support the proposed mitigation. Further, there is absolutely no assurance or guarantee that providing funding to MTA for improved Rapid Bus or other transit services would actually mitigate Alternative D traffic impacts at the intersection of Sepulveda Boulevard and Mariposa Avenue. Reducing demand by 76 vehicles or by 52 vehicles in the a.m. peak hour would require at least two buses. Providing this as a mitigation measure is absurd.

i) Sepulveda Boulevard and Rosecrans Avenue

i) Right Turn On Red Prohibitions Have Been Omitted – While the intersection geometry does reflect the recent widening of Sepulveda Boulevard, all calculations for conditions in 2008 and 2015 erroneously ignore the existing right turn on red prohibitions currently posted at this intersection. Westbound traffic on Rosecrans Avenue is prohibited from turning right on a red light on Monday through Friday from 6:00 to 9:00 a.m. and from 3:00 to 7:00 p.m. Eastbound traffic on Rosecrans Avenue is prohibited from turning right on a red light on Monday through Friday from 3:00 to 7:00 p.m. Northbound traffic on Sepulveda Boulevard is prohibited from turning right on a red light at any time.

ii) ATSAC/ATCS System Is Now Being Designed – Calculations in 2015 include capacity benefits with implementation of ATSAC/ATCS signal control. The County of Los Angeles is currently designing an ITS traffic signal system improvement project throughout the City of El Segundo. The Supplement incorrectly credits Alternative D for traffic signal system mitigation that will already be in place long before 2015. LAWA should contribute its “fair share” to the cost of the County improvement project as mitigation of Alternative D. The Supplement must also develop other measures to mitigate the traffic impacts of Alternative D at this intersection.

j) Eastbound I-105 On Ramp from Atwood Way Omitted – The Supplement failed to examine the impacts of Alternative D at the eastbound I-105 on

ramp on Atwood Way between Nash Street and Douglas Street. This two-lane on ramp includes ramp meters and the traffic impacts associated with Alternative D at this signalized intersection must be evaluated and mitigated as necessary.

- k) Eastbound I-105 On Ramp from Atwood Way Omitted – The Supplement failed to examine the impacts of Alternative D at the eastbound I-105 on ramp from Imperial Highway just east of Nash Street. This single lane on ramp includes ramp meters and the traffic impacts associated with Alternative D must be evaluated and mitigated as may be necessary.

21. Neighborhood Traffic Management Is Inadequately Analyzed and Unfunded – Page 35 of Technical Report S-2b indicates “Protecting neighborhoods is one of the four principles guiding the design of this alternative and its transportation analysis.” Neighborhood traffic management is then discussed in very broad and general terms but no specifics are identified. No funding for neighborhood protection is identified in either Technical Report S-2b or the Supplement, a very serious omission for “one of the four principles guiding” Alternative D.

Page 36 indicates “It is important to note that any Neighborhood Traffic Management Plan must have final approval by LADOT prior to implementation.” The Supplement must be corrected to indicate the responsible local agency such as the City of El Segundo or the County of Los Angeles will have responsibility for neighborhood traffic management plans within their respective jurisdictions.

22. Listing of Mitigation Measures Is Incomplete – Attachment E to Technical Report S-2b provides a listing of “Proposed Final Mitigations” for Alternative D. This listing omits the recommended new Lennox Boulevard Interchange with I-405 as well as the I-105 eastbound connections. It also omits freeway mainline widenings shown in Attachment G to Technical Report S-2b. It adds a “fair share” contribution toward a future widening of the southbound I-405 Freeway on ramp at El Segundo Boulevard but does not identify the scope of this proposed project. This listing also does not include any participation in neighborhood traffic management plans and it fails to provide “fair share” cost estimates for any of the proposed intersection or segment improvements. Attachment F to Technical Report S-2b, the Alternative Mitigation Plan for Alternative D without the Lennox Interchange and I-105 Ramps, contains many of the same errors and omissions identified above for Attachment E. As a result, the Supplement fails to incorporate all of the feasible mitigation measures to reduce significant traffic impacts of Alternative D.

23. Mitigation Measure Completion Not Coordinated With Alternative D Phasing – Table S4.3.2-11 beginning on Page 4-275 of the Supplement provides a

Ms. Christy H. Taylor
LAX Master Plan Alternative D Traffic Comments
October 28, 2003

listing of the various mitigation measures to be implemented in 2008. Table S4.3.2-12 beginning on Page 4-279 of the Supplement provides a listing of the various mitigation measures to be implemented in 2015. However, comparison of these tables to the proposed schedule for Alternative D as shown on Page 3-54 indicates several discrepancies in the proposed timing of the mitigation. As one example, mitigation measures at Imperial Highway and Main Street must be constructed prior to the scheduled completion of the proposed west employee parking structure in 2006, not in 2015 long after increased LAX employee traffic occurs along Imperial Highway. The timing of the construction of all of the proposed mitigation measures must be reevaluated to insure they will be operational prior to opening of the various major components in Alternative D.

24. Supplement Fails to Incorporate All Feasible Mitigation – LAWA must mitigate project traffic impacts at the locations that will be identified as part of the revisions in response to the numerous comments in this letter. Cost estimates for the necessary mitigation measures must be developed and the proportionate “fair share” contributions calculated for Alternative D. The Caltrans study guidelines require that mitigation measures include “financing, scheduling, implementation responsibilities, and lead agency monitoring” and these items must be added to the Supplement. Without addressing these numerous significant issues, the Supplement fails to incorporate all feasible mitigation measures to reduce significant traffic impacts.

Based on the numerous errors and omissions in the Supplement and Technical Report S2-b pointed out in this letter, the necessary reevaluation of Alternative D will likely disclose many additional significant traffic impacts. The various issues outlined in this letter must be carefully studied and evaluated before reaching any conclusion about the significance of traffic impacts, and the design of appropriate mitigation measures. The Supplement’s current conclusion, that most of the project impacts from Alternative D would be reduced to insignificance in the areas of transportation and circulation by implementation of the mitigation measures as proposed, is questionable in light of the myriad of technical problems in the analysis.

Respectfully submitted,

Tom Brohard and Associates

Licenses: 1976 / Professional Engineer / California – Civil, No. 24577
1977 / Professional Engineer / California – Traffic, No. 724

Education: BS / Civil Engineering / Duke University / 1969

Experience: 33 Years

Memberships: Institute of Transportation Engineers - Member
Orange County Traffic Engineers Council - Chair 1979-1980
American Public Works Association - Member

Expertise: Tom is a recognized expert in the field of traffic engineering. His background also includes responsibility for leading and managing the successful delivery of a variety of municipal contract services to numerous cities throughout Southern California for over 15 years.

Tom has extensive experience in providing transportation planning and traffic engineering services across Southern California. From 1972 through 1978, he conducted all traffic engineering investigations in the Second Supervisorial District in Los Angeles County. He has served as City Traffic Engineer/Transportation Manager/Engineer as follows:

- Bellflower 1997-1998
- Bell Gardens 1982-1995
- Huntington Beach 1998-present
- Lawndale 1973-1978
- Los Alamitos 1981-1982
- Oceanside 1981-1982
- Paramount 1982-1988
- Rancho Palos Verdes 1973-1978
- Rolling Hills 1973-1978, 1985-1993
- Rolling Hills Estates 1973-1978, 1984-1991
- San Marcos 1981
- Santa Ana 1978-1981
- Westlake Village 1983-1994

Since March 1998, Tom has served the City of Huntington Beach. As Interim Transportation Manager for the first 3 ½ years, he oversaw a staff of 20 including traffic engineers and transportation planners, traffic signal and street lighting personnel, and the signing, striping, and marking crews. Tom secured over \$3.5 million in grant funding for the City and managed the initial West Orange County Rail Feasibility Study. He recently completed a detailed review of the Circulation Element of the General Plan and prepared a Request for Proposal for the City's new traffic model. Other selected accomplishments during his previous regular office hours at City Hall included the following:

Tom Brohard and Associates

SAL00015 V

Consulting Transportation Engineer, Huntington Beach (10/2001 to 7/2002)

Primary duties in the capacity of consulting transportation engineer included:

- Identified study scope and reviewed traffic impact analysis reports prepared for development projects estimated to generate more than 100 peak hour vehicle trips.
- Established conditions of approval for proposed development projects and reviewed all related improvement plans.
- Established and approved truck haul routes associated with grading operations.
- Administered the City's Fair Share Traffic Impact Fee Program.
- Conducted traffic engineering investigations of citizen requests for traffic control device installation, modification, or removal.
- Prepared reports, correspondence, and work orders for traffic control devices.
- Prepared grant applications and obtained funding approval for various traffic safety improvements through Caltrans under the Hazard Elimination Safety Program (\$225,000) and from the California Energy Commission for battery back up units for traffic signals (\$300,000).
- As requested, attended meetings of the Public Works Commission and City Council to present reports involving traffic engineering and transportation planning items.
- As requested, represented the City in regional transportation planning studies including the Orange County Transportation Authority's Santa Ana River Crossings Study and the West Orange County Transit Needs Project Definition Study.

Interim Transportation Manager, Huntington Beach (3/1998 to 10/2001)

Served as a Division Head in the City's Department of Public Works, with primary responsibilities and accomplishments including:

- Active representation of the City in various regional transportation assignments including the Orange County Transportation Authority's Santa Ana River Crossings Study and the West Orange County Transit Needs Project Definition Study.
- Coordinated enhancements of the traffic signal master system involving 10 different projects totaling \$4.26 million, while only using \$360,000 of City matching funds.
- Provided advice and assistance regarding transportation matters to the Public Works Department, other departments, various commissions, and City Council.
- Presented transportation reports at meetings of the Public Works Commission, Planning Commission, and City Council.
- Assessed the traffic impacts of proposed development projects and recommended conditions of approval to mitigate traffic impacts.
- Provided technical advice, guidance, and assistance to the City's Transportation Division staff as well as others involved in project design and plan preparation for traffic engineering projects.
- Directed studies and investigations of installation, modification, or removal of traffic control devices including traffic signals; regulatory, warning, construction, and guide signs; crosswalks; school area controls; speed zoning; and pavement and curb markings.
- Developed the City's Fair Share Traffic Impact Fee Program with the supporting technical nexus study.

Other Key Projects During the Last Three Years Include the Following Assignments:

Critiques of Traffic Impacts in the Draft EIR and the Final EIR for the Proposed Wal-Mart in the City of Fremont in Alameda County; Prepared for Mark R. Wolfe & Associates (7/2002 to 3/2003)

Reviewed the traffic analysis in the June 2002 Draft Environmental Impact Report and related technical studies for the Fremont Wal-Mart, a project proposed to contain a 156,000 square foot Wal-Mart building with garden center and a tire and lube express station plus 45,000 square feet of business park development. Services included a detailed field review of the existing roadways and the surrounding area to document lane configurations and observe critical intersections during the afternoon peak hour. Numerous flaws and many errors were documented including omission of analysis of Saturday and construction traffic impacts, incomplete evaluation of the main project access and traffic impacts on the adjacent I680 Freeway Interchange, faulty methodology including low trip generation rates and skewed trip distribution, insufficient analysis of queuing traffic back from the adjacent major intersection, and mitigation measures which cannot be constructed without additional right of way and relocation of high voltage electrical transmission towers at the adjacent major intersection.

Subsequently, review of the responses to these comments in the November 2002 Final EIR and the December 2002 Recirculated Portions of the EIR for the project disclosed a number of the previous concerns had not been properly addressed, and a rebuttal was prepared. Review of the responses to these comments contained in the March 2003 Final EIR disclosed continuing errors and inconsistencies, and another rebuttal was prepared.

Critiques of Traffic Impacts Identified in the Draft EIR and the Final EIR for the Alpine Village Center in the Community of Alpine in San Diego County; Prepared for Shute, Mihaly, and Weinberger (6/2002 to 3/2003)

Reviewed the traffic analysis in the May 2002 Draft Environmental Impact Report and related technical studies for the Alpine Village Center in San Diego County. This project is proposed to contain a 58,000 square foot supermarket with pharmacy, 9,000 square feet of retail shops, eight fueling stations with mini-market, and a 3,000 square foot fast food restaurant with drive thru. Services included a detailed field review of the existing roadways and surrounding area to document lane configurations at critical intersections. Numerous flaws and many errors were documented including inconsistencies with Caltrans guidelines, faulty methodology involving excessive pass by trip reductions, insufficient analysis of diverted linked trips from the adjacent I8 Freeway, and inadequate mitigation measures regarding the loss of on street parking.

The responses to these comments in the January 2003 Final EIR were reviewed and many of the previous concerns had not been properly addressed. A rebuttal to the Final EIR was prepared and testimony was given at the March 28, 2003 San Diego County Planning Commission public hearing regarding the continuing inadequacies of the traffic analyses.

Critiques of Traffic Impacts Identified in the Draft EIR and the Final EIR for the 2000 Avenue of the Stars Project in Century City in the City of Los Angeles; Prepared for Tract No. 7260 Association, Inc. (9/2002 to 2/2003)

Reviewed the traffic analysis in the August 2002 Draft EIR for the 2000 Avenue of the Stars Project encompassing replacement of 680,000 square feet of office, theater, restaurant, retail, and health club uses with 780,000 square feet of office, restaurant, retail, and cultural uses a 9.2 acre site. Major findings of this review disclosed the following:

- Faulty methodology used independent, unrealistically high peak hour trip generation rates for the existing high turnover restaurants and other commercial uses by not properly considering internal walking trips, high parking rates, and business hours.
- An unrealistic Transportation Demand Management (TDM) Program was assumed to reduce peak trips from the proposed project, together with nominal penalties.
- General office trip rates consistent with a recently approved EIR for a nearby 791,000 square foot building should have been used for 2000 Avenue of the Stars.
- To generate the same number of trips as the existing uses, the 2000 Avenue of the Stars Project would have to be reduced by 200,000 square feet.

The responses to these comments in the November 2002 Final EIR for the project were reviewed and several previous concerns had not been properly addressed. This was documented and subsequently presented at public hearings on December 9, 2002 before a City Hearing Officer and on February 13, 2003 to the City Planning Commission.

Critique of Traffic Impacts Identified in the Draft EIR for the Vallejo Waterfront Project; Prepared for Adams Broadwell Joseph & Cardozo (2/2003)

Reviewed the traffic portions of the December 2002 Draft EIR for the redevelopment of 400 acres in the downtown area including a multimodal waterfront transportation facility, ferry parking, 1,560 residential units, 1,015,000 square feet of commercial/office, 33 acres of public park, and a 1,200 seat performing arts center were reviewed. Many flaws and errors were documented including the use of inappropriate baseline traffic count data, failure to document the assumption that traffic volumes have remained constant in recent years, arbitrary dismissal of potential seasonal traffic volume variations, no analysis of AM weekday peak traffic flow, inadequate replacement parking during construction of a large parking structure, failure to address traffic impacts on opening day for each of the three development phases, and failure to quantify, address, and mitigate construction traffic impacts.

Expert Witness Evaluation of Traffic Impacts Caused By Simultaneous Construction of Alameda Corridor Transportation Authority Projects; Prepared for Sullivan, Workman, & Dee (12/2002 to 2/2003)

Reviewed over 4,000 pages of various studies, plans, depositions, and other documents relating to construction of Alameda Corridor Transportation Authority projects adjacent to a software distribution business in the City of Vernon. The sequence of traffic lane and street closures was verified for multiple phases of construction associated with significant projects including the railroad trench in Alameda Street, the Santa Fe Avenue viaduct, the Washington Boulevard grade separation, the Soto Street bridge project, and the Downey Road bridge project. Traffic impacts of the simultaneous construction of these multiple

major projects were quantified by calculating volume/capacity ratios and determining the associated Level of Service for each construction phase at over 20 intersections in the surrounding area.

Urban Street Design Fundamentals Training, City of Torrance (11/2001 to 4/2002 and 10/2002 to 12/2002)

Provided 12 four-hour training sessions for the Engineering staff in the fundamentals of urban street design, focused on traffic/transportation engineering, covering these topics:

- Highway and driver characteristics
- Operational data and problem solving
- Design guidelines and standards
- Roadway studies
- Geometric design of streets
- Geometric design of intersections
- Data, problem solving, reports, and presentations
- Urban roadway fundamentals
- Intersection design principles
- Intersection capacity calculations/simulations
- Traffic impact reports
- Traffic signal guidelines and operations

Critique of Traffic Impacts Identified in the Transportation Impact Study for the Western Research Campus in the City of Richmond in Contra Costa County; Prepared for Adams Broadwell Joseph & Cardozo (11/2002)

Reviewed the transportation impact study for the redevelopment and expansion of research and development facilities totaling 473,000 square feet. Several flaws and errors were documented including the use of low trip generation rates, incomplete analysis of several critical nearby intersections, failure to properly address and mitigate increased vehicle trips on nearby I80 and I580 Freeway mainlines and interchanges, and failure to identify the developer's fair share contributions to intersection widening and to identify the schedule for the necessary improvements.

Evaluation of the Proposed Intersection of Mulholland Highway and Hazel Nut Court in Los Angeles County; Prepared for Seminole Springs Mobile Home Park (11/2002)

Conducted an evaluation of sight distance at the proposed intersection of Hazel Nut Court with Mulholland Highway adjacent to the Seminole Springs Mobile Home Park in the Santa Monica Mountains. This assignment involved field measurements and observations, review of improvement plans and conditions of approval for the approved subdivision, and meeting with Department of Public Works staff to discuss alternatives and accepted standards. Our concise report indicated the County's conditions of approval to provide a separate left turn lane for the eight home subdivision as well as sight lines for 50 mph traffic were both unnecessary. Testimony at the November 26, 2002 Los Angeles County Board of Supervisors hearing resulted in the Board rescinding both conditions of approval and the County dropping its plans to condemn a portion of adjacent mobile home park property.

Critique of Traffic Impacts Identified in the Draft EIR for North Yorba Linda Estates in the City of Yorba Linda in Orange County; Prepared for Shute, Mihaly, and Weinberger (9/2002)

Reviewed the traffic analysis contained in the July 2002 Draft Environmental Impact Report for North Yorba Linda Estates in the City of Yorba Linda in Orange County. The project encompassed three sites proposed to contain up to 688 single family residences and 383 senior housing residential units. Services included a detailed field review of the existing roadways and surrounding area to document lane configurations and observe critical intersections. Numerous flaws and many errors were documented including various omissions from the traffic study to analyze traffic impacts from an alternate land use involving a 2,000 student high school, to properly identify impacts associated with extension of Bastanchury Road as an arterial highway, and to identify construction impacts. The review also identified faulty methodology including the use of unrealistically low trip generation rates for both the single family residences and for the proposed senior housing units. Insufficient analysis involving neighborhood traffic intrusion and inadequate mitigation measures at impacted intersections as well as failures to provide fair share cost estimates and a timely implementation plan were also identified in the review.

Hacienda Road Traffic Calming Study, City of La Habra Heights (12/2001 to 9/2002)

Alternatives were developed to slow traffic speeds on Hacienda Road, a two-lane rural highway carrying over 17,000 vehicles per day. Services during this study included:

- Conducted a locally televised public meeting to gather community input.
- Reviewed traffic speeds at various locations along Hacienda Road.
- Analyzed all accident reports taken on Hacienda Road over the last six years.
- Conducted field observations to quantify specific areas where current traffic speeds and recent traffic accident history were higher than expected and desired.
- Developed traffic calming alternatives to slow traffic and presented them at locally televised meetings of the City's Public Works Advisory Committee and City Council.
- Prepared a grant application for \$360,000 of funding under the Federal Hazard Elimination Safety Program to install a mile of raised medians on Hacienda Road.

Critique of Traffic Impacts Identified in the Draft EIR for the Central Larkspur Specific Plan in the City of Larkspur in Marin County; Prepared for Shute, Mihaly, and Weinberger (7/2002 to 8/2002)

Reviewed the traffic analysis in the June 2002 Draft Environmental Impact Report and related technical studies for the Central Larkspur Specific Plan in the City of Larkspur in Marin County. The Specific Plan encompassed an area proposed to contain up to 126,000 square feet of floor space for commercial uses and between 86 and 106 residential units on seven parcels. Services included a detailed field review of the existing roadways and surrounding area to document lane configurations and observe critical intersections. Numerous flaws and many errors were documented including various omissions from the traffic study, faulty methodology, insufficient analysis, and inadequate mitigation measures. This critique, together with other significant errors throughout the Draft EIR, caused the City to retract this document.

Critique of Traffic Impacts Identified in Various Environmental Documents for Three Residential Subdivisions in the City of Pittsburg in Contra Costa County; Prepared for Adams Broadwell Joseph & Cardozo (8/2002)

Conducted a preliminary review of the environmental documents and associated traffic studies for three proposed residential subdivisions in the City of Pittsburg in Contra Costa County including San Marco Meadows (779 single family homes on a 231 acre site), Sky Ranch II (386 single family homes on a 167 acre site), and Heritage Pointe (125 single family homes and a small park on 22 acres). Many flaws and errors were documented including failures to:

- Properly address and mitigate increased vehicle trips on local residential streets, arterial intersections, and adjacent freeway segments and interchanges.
- Use higher trip generation rates for larger homes.
- Apply different trip distribution patterns for AM and PM peak hours.
- Fund necessary mitigation measures in a timely manner.

Traffic Safety Study, City of Rolling Hills Estates (4/2001 to 5/2002)

Conducted Phase I of the City's Traffic Safety Study including:

- Review of city wide traffic accident data for five years for 1996 thru 2000.
- Identified intersections and midblock segments exceeding expected thresholds.
- Calculated accident rates for collision prone locations.
- Reviewed candidate locations and identified five for detailed analysis.
- Performed detailed studies of the top five locations.
- Recommended various low cost and capital improvements for consideration.

Critique of Traffic Impacts Identified in the Proposed Extension of Corona and Valley View Avenues Draft EIR in the City of Norco; Prepared for C. Robert Ferguson (1/2002 to 4/2002)

Reviewed the Draft Environmental Impact Report and supporting traffic studies for the proposed extension of Corona and Valley View Avenues in the City of Norco. The work included preparation of a detailed report identifying many comments and concerns regarding the adequacy of the information contained in the documents as well as a detailed rebuttal to the City's response to these comments. Testimony was also provided at a Public Hearing of the Norco City Council on the documents and the proposed project to connect the two local streets to a major arterial highway, Hidden Valley Parkway.

Critique of Traffic Impacts Identified in the Proposed LAX Expansion Draft EIR; Prepared for Shute, Mihaly, and Weinberger/City of El Segundo (2/2001 to 3/2002)

Conducted a detailed review of the Draft Environmental Impact Statement/Environmental Impact Report for the expansion of Los Angeles International Airport as the documents related to traffic impacts in the City of El Segundo. Many comments and concerns were documented regarding the adequacy of the information provided in the Draft EIR and in the Technical Report for the Off-Airport Ground Access Impacts and Mitigation Measures developed for the three different airport expansion strategies in 2005 and in 2015.

Critique of Traffic Impacts Identified in Caltrans Route 118 at Donlon Road/Somis Road Intersection Improvements Initial Study/Environmental Assessment; Prepared for Shute, Mihaly, and Weinberger (12/2000 to 10/2001)

Conducted a detailed review of the Initial Study/Environmental Assessment and other documents prepared by Caltrans for improvements to the intersection of State Route 118 at Donlon Road/Somis Road (State Route 34) in the Community of Somis in Ventura County. The work included preparation of detailed reports and the development of alternative intersection improvements to reduce congestion at the intersection and to mitigate impacts to the community. Testimony was presented to the Ventura County Board of Supervisors at public hearings and assistance was provided to the community during mediation.

Key Projects Completed Over Three Years Ago Include the Following Assignments:

Public Works/Traffic Engineer, City of Bellflower

Served as the City's Public Works/Traffic Engineer, with principal accomplishments and assignments including:

- Preparation of the City's Five-Year Capital Improvement Plan.
- Obtained \$4.7 million to eliminate 28 at grade railroad crossings.
- Management of the Traffic Signal Master Plan Study.
- Performed development review and set conditions for 40 projects.
- Updated the signing and pavement markings at all 18 schools.
- Developed the Bellflower Boulevard Congestion Relief Project.
- Developed various ordinances and policies for consideration.

Traffic Impact Studies, Various Cities

Prepared traffic engineering studies and reports for various projects including a 90 home development in the City of Rancho Palos Verdes and a 110,000 square foot mixed use commercial project in the City of San Gabriel.

Lindero Canyon Road Extension Study, City of Westlake Village

Evaluated the traffic impacts associated with extension of a major arterial highway into Ventura County and prepared a detailed report for consideration.

Development Review of Various Projects, City of Westlake Village

Oversight of traffic impact studies with various development projects, including: Westlake North Specific Plan and Draft EIR (500 residential units, 40 acres of commercial and light industrial development and a 400-room hotel); the Westlake Spectrum Specific Plan and Draft EIR (750,000 square feet of light industrial/commercial development); the Trails Residential Development (40 custom single family homes); and the Three Springs Planned Development Permit (400 single family homes).

City-Wide Bicycle Master Plan, City of Westlake Village

Prepared and implemented the City's initial Bicycle Master Plan.

Euclid Street Corridor Study, County of Orange

Prepared an inventory of all traffic control devices on this highway and developed recommendations to improve traffic safety in the corridor.

School Zones, City of Bell Gardens

Prepared safe walking route to school maps for each of the 10 elementary schools in the City. Implemented signing and pavement marking improvements at each school and prepared city-wide evaluations of the need for adult crossing guards.

Engineering and Traffic Surveys for Speed Zoning, Various Cities

Conducted engineering and traffic surveys to establish enforceable speed limits in the Cities of Alhambra, Baldwin Park, Bell Gardens, Dana Point, Hidden Hills, Huntington Beach, La Habra Heights, Palos Verdes Estates, Paramount, and Westlake Village.

City-Wide Traffic Control Device Inventory, City of Torrance

Using aerial photography and ground level video, inventoried all traffic control devices including traffic signals, signing, striping, pavement markings, and curb markings. Developed recommendations for maintenance and removal of non-standard devices.

Federal Hazard Elimination Safety Projects, Various Cities

Obtained funding, designed, inspected, and administered construction contracts for traffic signal modifications for the Cities of Alhambra (65 intersections), Bell Gardens (15 intersections), Buena Park (30 intersections), Huntington Beach (10 intersections), Paramount (20 intersections), Rosemead (15 intersections), Santa Ana (60 intersections), and Westlake Village (3 intersections).

Traffic Signal Installations, Various Cities

Designed and administered various traffic signal projects for the Cities of Bell Gardens, Huntington Beach, Paramount, Rosemead, and Westlake Village.

Raised Pavement Marking Projects, Various Cities

Obtained funding and prepared specifications for installation of non reflective and reflective raised pavement markers on all arterials in the Cities of Alhambra, Bell Gardens, Buena Park, Huntington Beach, Irvine, La Habra Heights, Norwalk, Paramount, Rosemead, and Whittier.

COMMENTS

Los Angeles World Airports ("LAWA" or "the Applicant"), the operator of the Los Angeles International Airport ("LAX"), has published a Draft Master Plan Addendum¹ ("DMPA"), a Supplement to the Draft Environmental Impact Statement/Environmental Impact Report² ("Supplement"), and Airport Layout Plans Package on the modernization of LAX ("Project"). These documents supplement the Draft Environmental Impact Statement/Environmental Impact Report³ ("Draft EIS/EIR") and add discussion of Alternative D to the previously discussed Master Plan alternatives.

The comments below provide an analysis of the Supplement's failure to meet the requirements of CEQA and NEPA. These comments expand upon our previous comments on the Draft EIS/EIR and address new issues raised by the Supplement. (Comments on Air Quality and Human Health and Safety, LAX Master Plan Draft EIS/EIR (July 13, 2001) by J. Phyllis Fox, Ph.D., Attachment C to September 18, 2001 Comments Submitted on Behalf of the City of El Segundo by Shute, Mihaly & Weinberger ("2001 Fox Comments").)

The documents do not supply the data required for us to verify the calculations and modeling used to determine air quality impacts. El Segundo submitted requests to LAWA and the Federal Aviation Administration ("FAA") under the California Public Records Act and the Federal Freedom of Information Act in October 2003, seeking this important information. Although we have been informed that some or all of the information will be provided, we have not received it in time to prepare these comments. After receiving the requested data, we intend to review them and reserve the right to submit additional comments based on this review.

AIR QUALITY

I. THE BASELINE IS UNSUPPORTED AND FLAWED

The environmental baseline is the heart of a CEQA or NEPA analysis because the significance of environmental impacts is measured by the change

¹ LAX Master Plan Addendum, July 2003.

² LAX Master Plan, Supplement to the Draft Environmental Impact Statement/Environmental Impact Report, July 2003.

³ LAX Master Plan, Draft Environmental Impact Statement/Environmental Impact Report, January 2001.

from the baseline. Neither the Draft EIS/EIR nor the Supplement contains sufficient information to allow a subject matter expert to evaluate the accuracy of the air quality data for the 1996/1997, 2000, or No Action/No Project ("NA/NP") baseline conditions used in these documents. Supporting calculations are not included in the Draft EIS/EIR, the Supplement, or technical reports and appendices. Further, our requests to LAWA and FAA to produce the data necessary for a review of these calculations have not been responded to in time. However, a number of factors suggest, based on our careful review, that the baseline is flawed.

We previously pointed out discrepancies between the baseline emissions in the Draft EIS/EIR and the supporting technical appendices. (2001 Fox Comments, II.A, pp. 7-8.) The Supplement does not resolve these discrepancies. We previously commented that it is improper to evaluate off-airport emissions against future baselines. (2001 Fox Comments, II.B, pp. 8-9.) The Supplement continues to evaluate off-airport emissions against future baselines. (Supplement Table S4.6-10.) We previously commented that the NA/NP alternative does not fairly reflect future conditions because it assumes the airport can grow nearly unrestrained. The Supplement is silent on this issue. We previously noted that it was not possible to evaluate the projected NA/NP emissions because supporting calculations were not provided. The Supplement does not contain the supporting calculations. In addition to failing to address our previous comments on the baseline, the Supplement introduces a new problem by using an invalid ratio method to adjust baseline emissions.

I.A The Ratio Method Is Invalid

The on-site Project impacts for CEQA purposes are evaluated relative to the 1996 baseline emission inventory, which is stated to represent activity levels at LAX in 1996 and facilities as of 1997. (Draft EIS/EIR, p. 4-462.) The Supplement updated this baseline using ratios between emission model results from EDSM 3.2 and 4.11 for Alternative D.

Since publication of the Draft EIS/EIR in January 2001, the FAA has released an updated version of the Emissions and Dispersion Modeling System ("EDMS") used to develop airport emission inventories. The Supplement calculated emissions and concentrations resulting from Alternative D with both the old model version, EDMS 3.2, and with the new version, EDMS 4.11, for the year 2015. From these model runs for Alternative D, the Supplement developed ratios between the predicted emissions for each criteria pollutant. Rather than running the updated model version for the baseline, the Supplement used these ratios to develop revised baseline (1997) emissions and to quantify year 2000 emissions. The Supplement also applied this ratio method to estimate impacts

for Alternatives A through C and the NA/NP Alternative, previously analyzed using EDMS 3.2 in the Draft EIS/EIR. (Supplement, pp. 4-357/358 and Supplement Appx. S-E⁴, p. 4.)

As discussed in the following, this approach is scientifically flawed, does not yield comparable emissions data for the alternatives, and is therefore unacceptable. Compared to the old version, EDSM 3.2, the updated version EDSM 4.11 incorporates several technical changes that affect modeled emissions inventories including an updated emission factor database for aircraft; updated ground support equipment emission factors based on model year, power output, and fuel type; additional assessment of emissions from aircraft landing roll time-in-mode; inclusion of aircraft flight profile to model dispersion after takeoff and on approach; use of the most current dispersion modeling methods; and an improved characterization of aircraft plume dispersion behavior. (Supplement Appx. S-E, pp. 3/4 and 15/16.)

Obviously, differences among the alternatives in the annual number of aircraft, the fleet-mix, etc., will affect the results of modeled emissions and ambient concentrations. The evaluated alternatives are based on greatly differing airport capacities and/or regional distributions and, thus, the corresponding annual number of aircraft and fleet mix are substantially different. For example, the modeling for the NA/NP alternative and Alternative D assume a much lower number of annual aircraft operations (~780,000 flights/year) than either Alternatives A and B (~935,000 flights/year). (Supplement, p. 3-14.) Thus, using a constant ratio to adjust emissions for all alternatives would result in errors in emissions and invalidate the inter-alternative comparisons using this methodology. Consequently, emissions from all alternatives need to be remodeled using EDSM 4.11.

Further, while the Supplement states that ratios were developed for each criteria pollutant in year 2015 for Alternative D, these ratios are nowhere to be found in either the Supplement, the Supplement's extensive Technical Report⁵ ("TRS-4"), or its appendices. (Supplement, pp. 4-357/358 and Supplement Appx. S-E, pp. 3/4.) The Supplement also does not provide the modeling input/output files from the two EDSM versions, which supposedly form the basis for the calculation of these ratios. Clearly, the information provided in the Supplement is deficient and inadequate to verify any calculations.

⁴ LAX Master Plan Supplement to the Draft Environmental Impact Statement/Environmental Impact Report, Appendix S-E: Supplemental Air Quality Impact Analysis, June 2003.

⁵ LAX Master Plan Supplement to the Draft Environmental Impact Statement/Environmental Impact Report, Technical Report S-4: Air Quality, Attachment N: Incremental Emissions by Alternative and Year, July 2003.

Finally, the ratios between unmitigated operational emissions in the Draft EIS/EIR, Table 4.6-8 and the Supplement, Table S4.6-9, are not constant, nor even nearly so. For example, the ratios for VOC, SO₂, and PM₁₀ between the baseline and the NA/N Alternative, the baseline and Alternatives A through C, are drastically different. For VOC and SO₂ they are further different between the horizon years for each alternative. The ratios for PM₁₀ between the horizon years remain constant, however, they are different for the baseline, the NA/NP alternative and the Alternatives A through C. (See Table 1, attached to this document.) In a word, with the exception of the CO and NO_x ratio, it appears that none of the ratios for the other pollutants was applied consistently to derive operational emissions for the alternatives and year combinations. The Supplement has not fully disclosed the procedure that it used to revise the emissions calculations. In addition, it appears that errors were made in revising the emissions with the ratio method. We are unable to check the Supplement's calculations because adequate information was not provided.

I.B Underlying Data Set Questionable

In addition to the ratio method being scientifically flawed, it is unclear from the description provided in the Supplement, Section 4.6.3.4, which dataset was used to update calculations. As we pointed out in our earlier comments on the Draft EIS/EIR, the 1996 environmental baseline emissions for all criteria pollutants reported in Tables 4.6-6 of the Draft EIS/EIR differ substantially from those reported in the corresponding Draft EIS/EIR Air Quality Technical Report ("TR4"), Attachment C, which supposedly provides the support for emission estimates. (2001 Fox Comments, II.A, pp. 7-8.) The emission estimates reported in the Draft EIS/EIR are 14% to 47% lower than those indicated in the TR4. The Supplement does not comment on these discrepancies, nor does it specify which dataset the updated calculations are based on.

The Supplement does not contain any information to resolve the noted discrepancies. Thus, there is no creditable support for the baseline emissions used to evaluate the significance of impacts under CEQA. These discrepancies should be resolved and the Supplement and supporting technical reports of the Draft EIS/EIR recirculated for public review.

II. AIR QUALITY IMPACT ANALYSIS IS INADEQUATE

II.A New PM₁₀ And PM_{2.5} Standards Not Acknowledged

The Supplement did not analyze PM_{2.5} impacts and evaluated PM₁₀ impacts against the existing PM₁₀ standard of 30 µg/m³. We previously

commented on the Draft EIS/EIR's failure to evaluate PM_{2.5} impacts. (2001 Fox Comment, III.D, pp. 18/19.) The Supplement declined to analyze PM_{2.5} impacts despite the fact that it was known during the preparation of this document that a PM_{2.5} standard would be established and a lower PM₁₀ standard of 20 µg/m³ would go in effect in summer 2003. In fact, the Supplement states in Footnote 5 to Table S4.6-3 and Footnote 9 to Table 4.6-12 that "[o]n June 20, 2002, CARB approved the recommendation to revise the PM₁₀ annual average standard to 20 µg/m³ and to establish an annual average standard for PM_{2.5} of 12 µg/m³" and continues "[t]hese standards will take effect upon final approval by the Office of Administrative Law, which is expected in summer 2003." (Supplement, pp. 4-363 and 4-374.)

In fact, the Office of Administrative Law ("OAL") approved the amendments to the regulations for the State Ambient Air Quality Standards ("CAAQS") for particulate matter ("PM") on Thursday, June 5, 2003, before the publication of the Supplement in July 2003. The new standards became effective on July 5, 2003.⁶ These new standards should have been used to determine the significance of impacts from the proposed Project alternatives. The Supplement, in the face of clearly acknowledged indications that the standards would become effective before an alternative would be selected, still declined to analyze PM_{2.5} impacts and continued to evaluate PM₁₀ impacts against the old standard.

The Supplement justifies this questionable approach by arguing that "[u]ntil USEPA issues guidance on the implementation of the PM_{2.5} ambient air quality standards, that agency has recommended that compliance with the PM₁₀ standards be considered as a surrogate for compliance with the PM_{2.5} standards, and the analysis in this document follows that guidance," citing 1997 U.S. Environmental Protection Agency ("U.S. EPA") guidance. (Supplement, p. 4-363 and footnote 116.) This guidance is irrelevant to the instant case for a large number of reasons.

First, the cited EPA guidance memo was intended as an interim guidance "for meeting new source review (NSR) requirements under the Clean Air Act (Act), including the permit programs for prevention of significant deterioration

⁶ California Air Resources Board, Ambient Air Quality Standards for Suspended Particulate Matter (PM) and Sulfates, Rulemaking To Consider Amendments To Regulations For The State Ambient Air Quality Standards For Suspended Particulate Matter (PM) And Sulfates, June 20, 2002 Hearing, <http://www.arb.ca.gov/regact/aaqspm/aaqspm.htm>; accessed October 27, 2003.

of air quality (PSD).” (U.S. EPA 10/97.)⁷ It was *not* intended to be used as guidance for CEQA or NEPA purposes.

Second, the guidance was intended to be valid until the “significant technical difficulties that now exist with respect to PM_{2.5} monitoring, emissions estimation, and modeling” were resolved. Some of these issues were never applicable to CEQA or NEPA review. Further, since publication of the guidance memo in 1997, most of these technical difficulties have been addressed. A large body of information has been developed, incorporated into methodologies, and tested in practice since publication of the guidance memo six years ago.⁸ For example, a nationwide monitoring network for PM_{2.5} has been implemented. As of 2001, a total of 82 twenty-four-hour mass monitors and 21 continuous mass monitors (“CMM”) had been deployed and 15 new CMM sites were planned.⁹

Third, there are two sets of standards, federal and state. The cited EPA guidance does not apply to state standards, which were adopted before the Supplement was released.

Fourth, PM₁₀ and PM_{2.5} are separate and distinguishable pollutants with separate and distinguishable effects, including serious health effects. To address this issue, the U.S. EPA in 1997 promulgated a new national ambient air quality standard for PM_{2.5} of 15 µg/m³ annual average. (62 FR 38652¹⁰.) The ambient air quality standards for PM_{2.5} are much lower than for PM₁₀. By using the higher PM₁₀ ambient air quality standards, the Supplement has substantially underestimated the impacts of all alternatives.

Finally, essentially 100% of the Project’s operational emissions originate from combustion sources, *e.g.*, aircraft, ground support equipment, passenger cars. The major fraction of the particulate matter emissions from combustion sources is typically smaller than 2.5 microns in size, *i.e.* PM_{2.5}, rather than PM₁₀. For example, the PM_{2.5} fraction of particulate matter emissions is 92% for diesel

⁷ U.S. Environmental Protection Agency, Office of Air Quality Planning and Standards, Interim Implementation of New Source Review Requirements for PM_{2.5}, Memorandum from John S. Seitz, Director Office of Air Quality Planning and Standards, October 21, 1997.

⁸ See U.S. Environmental Protection Agency, Technology Transfer Network, Ambient Monitoring Technology Information Center, PM 2.5 Monitoring Information, <http://www.epa.gov/ttn/amtic/amticpm.html>, accessed October 28, 2003.

⁹ California Environmental Protection Agency, Air Resources Board, 2001 California PM_{2.5} Monitoring Network Description, August 2001; <http://www.arb.ca.gov/aqd/pm25/pmfnet01.htm>, accessed October 28, 2003.

¹⁰ National Ambient Air Quality Standards for Particulate Matter: Final Rule, Federal Register, v. 62, no. 138, July 18, 1997.

vehicle exhaust, 93% for gasoline vehicle with catalysts exhaust, and 99% for aircraft exhaust. The PM_{2.5} fraction of particulate matter emissions from stationary internal combustion engines firing gasoline or diesel, *e.g.*, heaters, typically range from 87% to 99%.¹¹ Thus, well over 90% of the operational particulate matter emissions from the Project are PM_{2.5}. PM₁₀ standards are therefore an inadequate substitute for evaluation of compliance with PM_{2.5} standards. PM_{2.5} must be properly analyzed, and standards appropriate to this more prevalent pollutant should be used, to assure that the adverse environmental and health impacts of PM_{2.5} emissions are properly disclosed.

II.B The Air Quality Analysis Is Piecemealed

The Supplement used EDMS to convert the emissions into projected ambient air quality concentrations. These were compared to ambient air quality standards to determine if the various alternatives would cause new violations of or significantly contribute to existing violations of ambient air quality standards. The resulting ambient concentrations for unmitigated emissions are included in Table S4.6-12 and their significance summarized in Tables S4.6-15 and S4.6-17. The resulting ambient concentrations for mitigated emissions are included in Table S4.6-22 and their significance summarized in Tables S4.6-24 and S4.6-26.

Inspection of these tables indicates that the Supplement, and the Draft EIS/EIR as a whole, has improperly piecemealed the air quality analysis. The tables that report significance report it separately for modeled ambient air concentrations resulting (a) from on-airport operational plus construction emissions and (b) from off-airport operational emissions. This is an impermissible approach. Pollutant concentrations and their significance should be reported for the Project as a whole, to disclose the cumulative effects of on-airport, off-airport, and construction emissions.

The Supplement, and the Draft EIS/EIR, should have evaluated ambient air concentrations resulting from the combined emissions of the Project, *i.e.* on-airport operations plus off-airport operations plus construction, for every single year for every alternative. In other words, emissions from on-airport and off-airport operations plus the construction emissions should have been modeled for every year of the Project. The off-airport emissions cannot be separately modeled from the operational emissions, as they occur simultaneously and affect the ambient air quality.

¹¹ California Air Resource Board (CARB), Determination of Particle Size Distribution and Chemical Composition of Particulate Matter from Selected Sources in California, NTIS Report PB89-232805, June 30, 1989, Figure 5.2-2.

By failing to do this, the Supplement, and Draft EIS/EIR have failed to disclose the full impacts of the Project. Further, had all parts of the Project been combined into a single analysis, the air quality impacts would have likely been much higher than disclosed in the Supplement.

II.C Future Background Concentrations Are Invalid

The standard approach to evaluating air quality impacts uses dispersion models to convert project emissions into increases in ambient concentrations of each pollutant. These incremental concentrations are then added to background ambient concentrations to estimate ambient concentrations after the project is built. These projections are then compared with ambient air quality standards to determine if the project would cause a significant air quality impact.

It is standard practice to use the maximum measured existing ambient concentration at the nearest monitoring station as the background in these calculations. The Draft EIS/EIR and Supplement, however, deviate substantially from the accepted approach and estimate future background concentrations using a linear rollback approach. This approach was used in the 1997 AQMP for a different purpose to determine if the proposed region-wide controls would bring the basin into compliance with standards. (Draft EIS/EIR, Appx. G¹², p. 45.) This approach assumes that changes in emissions will change ambient air concentrations proportionally. We previously commented on the inappropriate use of this methodology in the Draft EIS/EIR, noting that it resulted in very substantial reductions in future background concentrations that hide significant ambient air quality impacts. In particular, it reduces the background carbon monoxide ("CO") concentration by nearly a factor of two and hides what would otherwise, using a standard and more accurate analysis, be identified as violations of ambient air quality standards on CO. (2001 Fox Comments, II.B, pp. 8/9.)

In fact, the CEQA Guidelines published by the South Coast Air Quality Management District ("SCAQMD") contain a section on developing EIR baseline information, which clearly states that "[m]onitoring station data should be used to provide background concentration levels of criteria pollutants." (SCAQMD CEQA Guidelines 04/93¹³, p. 8-2) Also, SCAQMD recently published a methodology which is intended as assistance for other public agencies in using the mass daily significance thresholds for construction and operation published

¹² LAX Master Plan Supplement to the Draft Environmental Impact Statement/Environmental Impact Report, Appendix G: Air Quality Impact Analysis, June 2003.

¹³ South Coast Air Quality Management District, CEQA Air Quality Handbook, April 1993.

in the District's 1993 CEQA Air Quality Handbook. (SCAQMD 06/03¹⁴.) These significance thresholds are used to determine a project's significant adverse regional effects on air quality when preparing an air quality analysis for CEQA or NEPA analyses. The methodology is based on the use of the peak measured existing ambient concentration at the nearest monitoring station over a period of three years to determine whether or not construction activities create significant adverse localized air quality impacts. While this methodology is intended for projects smaller than 5 acres, it nonetheless demonstrates SCAQMD's standard practice of using the peak ambient concentration of a pollutant at the nearest monitoring station as the background concentration for modeling.

We further note that the future background concentrations of CO used in the Supplement are inconsistent with the SCAQMD estimate of average annual day CO emissions for the South Coast air basin and projected future 1-hour and 8-hour CO concentrations. (SCAQMD Table 1 through 3¹⁵.) SCAQMD Table 1 indicates that CO emissions are projected to decrease by 24% between the year 2000 and the year 2020. SCAQMD Table 2 indicates that 1-hour CO concentrations in Los Angeles are projected to decrease by 24%. SCAQMD Table 3 indicates that 8-hour CO concentrations in Los Angeles are projected to decrease by 22% to 24%. In comparison, the air quality analyses in the Supplement assume the year 2015 8-hour CO background concentration would decrease from 9.4 ppm in the year 2000 (Supplement, Table S4.6-5) to 3.4 ppm in the year 2015 (Supplement, Table S4.6-2) or by 64%. Similarly, the Supplement assumes the year 2000 1-hour CO background concentration would decrease from 11 ppm in the year 2000 to 4.2 ppm in the year 2015, or by 61%. Thus, the Supplement has underestimated ambient CO impacts by using an anomalously low future background concentration.

III. CONSTRUCTION EMISSIONS ESTIMATES ARE FLAWED

The Supplement presents a revised construction impact analysis, which results in substantially lower construction emissions and ambient impacts. The main text of the Supplement, Section 4.6, does not alert the reader to this substantial reduction. It must be discovered, for example, by comparing Table 4.6-10 in the Draft EIS/EIR with Table S4.6-11 in the Supplement. The Supplement provides no explanation or justification for the dramatic decrease in CO, volatile organic compounds ("VOC"), sulfur oxides ("SOx"), and PM10 and increase in nitrogen oxides ("NOx) emissions in the Supplement, compared to

¹⁴ South Coast Air Quality Management District, Draft Localized Significance Threshold Methodology, June 19, 2003; <http://www.scaqmd.gov/ceqa/hdbk.html>, accessed October 28, 2003.

¹⁵ See www.aqmd.gov/ceqa/hdbk.html, CO Concentrations, Tables 1-3, accessed October 28, 2003.

the Draft EIS/EIR. As detailed below, even though we have not yet received the data needed to review the modeling, there is ample reason to suspect that the construction emission estimates are flawed and fail to disclose the impacts of the proposed construction.

III.A Construction Emissions Estimates Are Unsupported

The Supplement contains no support for the new construction emission estimates beyond a few conclusory and summary paragraphs in Appendix S-E, Section 2.1.2. Hundreds of individual factors and assumptions go into a construction emission estimate. Construction exhaust emissions are estimated from an inventory of equipment that will be deployed as a function of time. This is referred to as activity data. For each piece of equipment, *e.g.*, loader or scraper, an emission factor in grams per brake horsepower hour (“bhp-hr”), equipment size in horsepower, a load factor, a usage factor, and fuel type must be specified. Construction fugitive dust emissions are typically estimated from disturbed area, control efficiencies, and emission factors in pounds per acre (“lb/acre”) disturbed per unit time. This information should be provided in a comprehensive and complete manner; it has not been.

The new analysis of the Supplement employs the same ratio method used in the Draft EIS/EIR to calculate emissions from construction equipment, and a new model, CARB’s OFFROAD Model, to estimate construction emissions. (Supplement, Appx. S-E, p. 3.) First, emission factors for off-road construction equipment were revised based on CARB’s OFFROAD model and emission factors for on-road equipment were revised based on CARB’s EMFAC 2002 model. Alternatives C and D were then analyzed using the updated emission factors. The ratio of old Alternative C emissions to new Alternative C emissions was then calculated and used to adjust old Alternatives A and B emissions to the new basis. (Supplement, Appx. S-E, p. 3.) Specifically, “[c]onstruction duration and activity levels were developed for Alternative C. Construction emission estimates for Alternatives A and B were based on ratios of construction areas for Alternatives A and B to those areas for Alternative C. (Draft EIS/EIR, Appx. G, p. 4.)

None of this information is provided in a comprehensive manner in the documents, and some critical information has been omitted. For example, nowhere in the air quality section can the above quoted “ratio of construction areas” or even the construction areas themselves be found. When information is provided, it is scattered throughout various documents, *i.e.* the Draft EIS/EIR, the Supplement, and their various technical appendices and technical reports. Because no comprehensive overview is provided regarding where the various pieces to the analysis can be found, the reader can only piece together the

information gleaned from the various documents with painstaking detective work. Some of the information is mislabeled and, consequently hard to find. For example, construction activity data used to develop the construction emissions inventory for Alternative D is presented in Attachment C to Technical Report S-4 of the Draft EIS/EIR instead of in Attachment D as claimed by the Supplement. (Supplement, Appx. S-E, p. 2.) Further, some of the information provided in appendices is illegible due to poor scanning and reproduction. See, for example, the "Resource Calculations (Truck Trips)" in Appendix E to TR4 of the Draft EIS/EIR.

This combination of errors, omissions, illegible documents, and the lack of a clear methodology description makes it impossible to comprehensively review and comment on the construction emissions and related air quality impact analysis. El Segundo has requested supporting calculations and data files from LAWA and FAA, but we have not received the necessary information in time to utilize them in our comments.

III.B Ultra-low Sulfur Diesel Not Required As Mitigation

The Supplement claims that SO_x emissions were estimated from sulfur limits set by SCAQMD Rule 431.2¹⁶, which requires that all liquid fuels sold in the SCAQMD district are low sulfur fuels that contain no more than 500 parts per million by weight ("ppmw") sulfur through June 1, 2006 and 15 ppmw thereafter. However, low sulfur fuel is more expensive than high sulfur fuel. Thus, there is an economic incentive for contractors to import less expensive high sulfur fuel from outside of the SCAQMD, *e.g.*, from Nevada, unless a mitigation measure for the Project specifically requires the use of low sulfur fuel with the sulfur contents assumed in the construction emission calculations. The proposed mitigation measures, however, do not require the use of low sulfur fuel in construction equipment. (Supplement, Table S4.6-18.) In fact, one of the construction mitigation measures contemplates the use of Lubrizol fuel (PuriNO_xTM), which is an alternative diesel formulation blended from 500 ppmw diesel. Thus, there is no assurance that low sulfur fuel would be used for Project construction.

Further, the Supplement quoted January 1, 2005 as the effective date for the reduction of fuel sulfur content to 15 ppmw sulfur. In fact, the effective date has been extended to match a later compliance date adopted by the California Air Resources Board, *i.e.* no later than June 1, 2006, which is also applicable to refiners and importers in the South Coast District. Thus, 500 ppmw sulfur diesel

¹⁶ South Coast Air Quality Management District, Rule 431.2. Sulfur Content of Liquid Fuels, Amended September 15, 2000.

will be locally available for another 18 months for construction activities. The DEIS/EIR and Supplement assume that construction emissions for Alternatives A through C and the NA/NP alternative would peak in 2004 and for Alternative D in 2005. Thus, by assuming the effective date for the reduction of diesel fuel sulfur content to 15 ppmw to be January 1, 2005, construction emissions for Alternative D will be substantially underestimated, because the use of ultra-low sulfur diesel will not be mandated for another 18 months beyond the assumed date. Only during the later phases of construction will ultra-low (15 ppmw) sulfur diesel be the only fuel available in California. However, this also does not preclude construction companies to import diesel with higher sulfur content from Nevada, which has no such regulation.

The construction SO_x emissions should be revised to use higher sulfur fuel, or the mitigation measures expanded to specifically require the use of ultra-low sulfur fuel, meeting the 500 ppmw and 15 ppmw limits assumed in the emission calculations.

We also note that ultra-low sulfur diesel fuel is currently available within the South Coast. SO_x emissions from Alternatives A, B, and C remain significant after mitigation. (Supplement, Table S4.6-23.) Thus, all feasible SO_x mitigation is required. It is feasible to use only ultra-low sulfur diesel (15 ppmw) for Project construction. Thus, the list of construction mitigation measures in Table S4.6-18 should be expanded to require the use of only ultra-low sulfur diesel fuel.

III.C Assumed Fugitive Dust Control Efficiency For Watering Not Revealed

The Draft EIS/EIR proposed watering as a mitigation measure for dust control. (Draft EIS/EIR, Table 4.6-16.) We previously commented that SCAQMD Rule 403 requires implementation of best available dust suppression control measures and thus the proposed project cannot claim credit for this measure as mitigation. (2001 Fox Comments, IV.A, pp. 21-22.) In response, the Supplement removed this measure from the list of required mitigation measures, listed it as an applicable requirement (Supplement, p. 4-364), and estimated fugitive dust PM₁₀ emissions assuming "water is applied to control dust, as required by SCAQMD Rule 403." (Supplement, Appx. S-E, p. 2.)

However, watering is not the only dust control measure required in SCAQMD Rule 403. It is unclear whether only watering is assumed in the emission calculations, or the complete list of mitigation measures required by SCAQMD Rule 403. We presume the former for purposes of these comments because other requirements of SCAQMD Rule 403, *e.g.*, use of soil stabilizers, are still listed as mitigation in Table S4.6-18. (*See* Comment V.B.4.)

The Draft EIS/EIR assumed that watering would reduce PM10 by 90% to 95%. (Draft EIR/EIS, Table 4.6-16, p. 4-516.) This control range is unrealistic. If the Supplement likewise assumed 90% to 95% control, it has substantially underestimated both unmitigated and mitigated fugitive PM10 emissions. Typical control efficiencies of watering at construction sites have been estimated at 50%.¹⁷ For example, the SCAQMD in its CEQA Guidelines for dust control during grading assumes control efficiency ranges for watering from 34 to 68% during grading and 45 to 85% for unpaved roads, parking areas, and staging areas. (SCAQMD 04/93,¹⁸ Table 11-4.)

The Supplement does not indicate how much water would be applied, or, alternatively, establish any criteria, such as opacity limits, to assure that dust is effectively controlled. Large amounts of water would be required for dust control. This would potentially result in significant water impacts that have not been identified or evaluated. Further, even if large amounts of water are applied, it is not possible to achieve high control efficiencies using only water on these types of soil.

Thus, it is not clear that the (undisclosed) assumption as to fugitive dust control efficiency would actually achieve the assumed control efficiency. The Supplement is silent on mitigation effectiveness and the methods that would be used to monitor the implementation and effectiveness of the assumed, but not disclosed, control effectiveness. The Supplement should be revised to include the fugitive dust calculations and all assumptions used in preparing them, most notably, the dust control efficiency, watering frequency, and amount of applied water. The assumptions that fugitive dust calculations were based on should be stated in the Supplement, required as conditions of Project approval, and noted directly on all final construction drawings.

III.D Emission Reductions Not Supported

The Supplement estimates reductions in construction emissions that would be achieved for the peak year. (Supplement, Table S4.6-18.) However, the Supplement is silent on how these reductions were estimated. They appear to be inconsistent with the mitigation measures that are proposed.

¹⁷ PEDCo Environmental Specialists, Investigations of Fugitive Dust Sources - Emissions and Control. Prepared for the Environmental Protection Agency, OAQPS, Contract No. 68-02-044, May 1977.

¹⁸ South Coast Air Quality Management District ("SCAQMD"), CEQA Air Quality Handbook, April 1993.

III.D.1 NOx Reductions

The Supplement assumes that the proposed mitigation measures would reduce 300 to 1,100 ton/yr of NOx. (Supplement, Table S4.6-18.) This amounts to 22% of the total NOx from construction activities.¹⁹ However, only one of the proposed mitigation measures, a requirement to specify a combination of construction equipment using “cleaner burning diesel” fuel and exhaust emission controls, would reliably reduce NOx emissions. The various controls included in this measure – catalytic oxidizers, particulate traps, exhaust gas circulation, alternate fuel – are not capable of achieving a fleet-wide 22% NOx reduction, even if every single measure were required on every single piece of construction equipment.

This is an important issue because the air quality analysis in Table S4.6-22 indicates that the mitigated, combined operational and construction air pollutant ambient concentrations for annual average NOx in 2015 are very close to the significance threshold of 0.053 ug/m³. If construction NOx emissions were substantially higher than claimed, and we believe they likely are, the Project would result in new, unidentified violations of the annual average NO₂ ambient air quality standard for all alternatives in 2015.

Catalytic oxidizers remove VOCs and CO, not NOx. Particulate traps remove PM10, not NOx. Lubrizol fuel, which is presumably PuriNOx™, the only alternative Lubrizol fuel we are aware of, does remove NOx. However, it was verified by CARB on January 31, 2001²⁰ as achieving only a 14% reduction in NOx compared to CARB diesel. Thus, even if it were used in 100% of the diesel-fueled construction equipment, it would remove less than 14% of the overall NOx emissions because a portion of the construction emissions are from gasoline-fueled construction vehicles, delivery trucks, and commuting workers who predominately drive gasoline-fueled vehicles.

Finally, the Supplement proposes the use of diesel engines with exhaust gas recirculation (“EGR”) for NOx control. (Supplement, Table S4.6-18.) However, EGR-equipped, diesel-fueled, off-road construction equipment is not commercially available. EGR retrofit systems are being introduced, but thus far, only for on-road trucks. Currently, a large number of diesel passenger cars use EGR under some operating conditions (low speeds and low loads).

¹⁹ Estimated as [(Table S4.6-21 emissions) - (Table S4.6-11 emissions)]/(Table S4.6-11 emissions).

²⁰ Letter from Dean C. Simeroth, Chief, Criteria Pollutants Branch, to Thomas J. Sheahan, Lubrizol, January 31, 2001.

(Guibet 1999²¹.) There are also several hundred systems operating on Volvo and Cummins on-road engines in Europe and Asia and several demonstrations are under way in the U.S. (MECA 01/03²².) EGR works well for highway trucks because they have a constant supply of air as they move down the road but off-road equipment does not. Thus, enhanced fuel delivery, *i.e.* electronic injection, is more feasible for off-road applications such as construction equipment, because of their duty cycle. We are not aware that this technology is commercially available for the type of equipment that would be used to construct the Project.

Further, EGR technology results in secondary impacts that were not addressed in the Supplement. EGR can cause increases in particulate emissions and is a potential source of deposits in the intake system and in the combustion chamber of diesel engines. Thus, the large-scale use of EGR for construction of this project cannot occur without the use of detergent additives. See, for example, discussion in Guibet 1999 at page 463.

The majority of the other mitigation measures in Table S4.6-18 would only reduce fugitive PM10, not construction NOx exhaust emissions. The only other mitigation measure that would reduce NOx is the use of electricity from power poles rather than diesel-powered generators. Emissions from these generators are a tiny fraction of construction NOx emissions, less than 1% of the total construction NOx emissions, and even so the Supplement concedes that it cannot succeed in eliminating these emissions ("cannot completely eliminate need for portable generators"). (Supplement, Table S4.6-18, p. 4-389.) The proposed mitigation fails to specify either a specific fraction of electrical demand that would be power pole versus diesel-generator or any specific percent reduction in NOx for the diesel-powered portion of the electrical demand.

Thus, it is not clear how the Supplement proposes to achieve the 22% reduction in NOx emissions assumed in the mitigated construction emission analysis in Section 4.6.8.5. The assumed 22% is unsupported and unrealistic and results in the understating of impacts.

²¹ J.C. Guibet and E. Faure-Birchem, *Fuels and Engines: Technology, Energy, Environment*, Editions TECHNIP, Paris, France, 1999.

²² Manufacturers of Emission Controls Association, *Retrofit Emission Control Technologies for On- and Off-Road Diesel Engines*, January 16-17, 2003.

III.D.2 CO and VOC Reductions

The mitigated construction emissions assume that only 2 to 3% of the CO and 2 to 6% of the VOCs emissions would be reduced by the proposed mitigation program.²³ This is inconsistent with the post-combustion control mitigation measure, which includes the use of catalytic oxidizers, unless the Supplement has assumed that catalytic oxidizers would only be used on a very few pieces of equipment.

Catalytic oxidizers can remove up to 90% of both the CO and VOC. (MECA 01/03.) Catalytic oxidizers can be used on virtually all equipment that will be used to construct the Project. However, the Supplement has apparently assumed that only about 2 to 3% of the equipment would use catalytic oxidizers. The Supplement should be revised to require the use of catalytic oxidizers on all equipment, where feasible. A registered professional engineer should be required to certify that the use of an oxidizer is infeasible, where claimed.

IV. OPERATIONAL EMISSIONS ESTIMATES ARE FLAWED

The operational air quality impact analysis suffers from a number of problems including the overestimate of the baseline (*see* Comment I.A), the use of the wrong baseline (*see* Comment II.C), overestimates of control efficiencies that can be achieved with implementation of mitigation measures (*see* Comments III.D, IV.A, and IV.B), and substantially underestimates off-airport emissions because traffic assumptions are seriously flawed (*see* Comment IV.C).

We suspect that the combination of these factors resulted in substantial underestimates of mitigated incremental emissions from on-and off-airport operations. The Supplement now concludes that in 2015 NO₂ and SO₂ ambient air quality concentrations for all alternatives and CO for Alternatives A, B, and C would be less-than-significant. (Supplement S4.6-26.) Had the Supplement used more realistic assumptions for traffic emissions and mitigation control efficiencies and compared the incremental operational emissions to the correct baseline emissions, more air quality impacts would likely be significant after implementation of the proposed mitigation.

IV.A Claimed Emissions Reductions Are Flawed And Unsupported

We previously commented that many of the estimated emissions reductions were unsupported in the record and demonstrated this lack of data

²³ Estimated as [(Table S4.6-21 emissions) - (Table S4.6-11 emissions)]/(Table S4.6-11 emissions).

for the conversion of ground support equipment ("GSE") to electric power. However, as we pointed out, all other mitigation measures had similar problems. (2001 Fox Comment, II.D, p. 11/12.) The Supplement contains very limited additional information to address these problems.

For example, the Supplement added two short paragraphs on the conversion of GSE and proposes "the virtual elimination of GSE emissions" beyond the "requirements of the memorandum of understanding ("MOU") with CARB" through "incentives and tenant lease requirements." (Supplement, TRS-4, Appx. SE, p. 40.) The Supplement does not specify what these incentives and lease requirements would be, when they would be implemented, and how many vehicles they would affect.

Presumably, the assumptions that went into estimating the emission reductions attributable to the conversion of GSE to electric power have not changed, yet the range of potential emission reductions has changed considerably for most pollutants. The Draft EIS/EIR previously reported ranges of potential emissions reductions in 2015 of 250–450 tons per year ("ton/year") for NO_x, 100–130 ton/year for VOC, and 2000–2500 ton/year for CO. The Supplement now reports 400–600 ton/year for NO_x, 1600–1900 ton/year for VOC, and 2300–2800 ton/year for CO. (Draft EIS/EIR, p. 4-514; Supplement, p. 4-389.) The Supplement fails to provide an explanation what caused these considerable differences or why the proportion of potential emission reduction between the pollutants has changed so drastically. Further, it is unclear which end of the control range was applied to calculate the mitigated emissions.

An EIR must be transparent enough to allow a subject matter expert to evaluate the accuracy of its estimates. The Supplement is silent on the assumptions that went into these calculations. Thus, the air quality analysis is entirely inadequate and must be revised.

IV.B ITC Emissions Reductions Are Overestimated For Alternative D And Not Applicable To Alternatives A Through C

The Supplement claims that substantial emission reductions can be achieved through the construction of five additional intermodal transportation centers ("ITCs"), so-called "flyaways." The Supplement further maintains that each of these ITCs would reduce traffic – and associated air emissions – by 750,000 vehicle round trips per year. (Supplement, TRS-4, Appx. S-E, p. 40.) The Supplement further claims that this mitigation measure is applicable to and proposed for all four alternatives and specifically lists the measure as "quantifiable." (TRS-4, Appx. S-E, p. 40.)

However, review of the description of alternatives shows that no such ITCs are planned for Alternatives A, B, and C and only one ITC is planned for Alternative D. (Draft Master Plan²⁴, Chapter 3 and DMPA, Section 2.2.) Obviously, the Supplement can only claim emission reduction credits for mitigation measures that will be implemented, not for some hypothetically feasible measures, yet it appears that the Supplement has applied the control efficiency of this measure to all four alternatives. (TRS-4, Appx. S-E, p. 44.)

The Supplement estimates potential emissions reductions from ITCs of 80-100 ton/year NO_x, 50-60 ton/year VOCs, 1000-1200 ton/year CO, 1-2 ton/year SO₂, and 15-20 ton/year PM₁₀. (Supplement, p. 4-392.) The Supplement does not provide information on how the annual reduction of 750,000 vehicle round trips per ITC was derived, nor how these round trips were converted to emissions.

Application of these potential emission reductions to unmitigated traffic emissions results in substantially underestimated mitigated emissions and resulting modeled ambient air quality concentrations from on-airport and off-airport traffic for all alternatives. The measure should not have been applied to Alternatives A through C at all, and only one fifth of these potential emissions reductions should have been applied to Alternative D, as only one ITC will be built and not five. This would have substantially increased emissions for all criteria pollutants and likely resulted in more significant ambient air quality impacts than were found by the Supplement.

IV.C Traffic Emissions Are Underestimated

The air quality analysis includes estimates of on-airport and off-airport operational emissions associated with traffic based on the number of vehicle trips associated with airport operations. Review of both the Draft EIS/EIR's and the Supplement's traffic analyses reveals that LAWA substantially underestimated traffic associated with all alternatives. (See comments by Tom Brohard and Associates, Attachment B to September 18, 2001 El Segundo comment letter, and Attachment 2 to the current comment letter.) Thus, LAWA has also underestimated operational emissions associated with traffic.

V. PROPOSED MITIGATION PROGRAM IS INADEQUATE

The construction and operational air quality mitigation program proposed in the Supplement are inadequate because the measures are not enforceable, the

²⁴ LAX Draft Master Plan, November 10, 2000.

proposed measures would reduce very little of the emissions, and all feasible mitigation measures have not been identified. The descriptions of the mitigation measures in the Supplement are too general to assure that they will actually be implemented. Enforceability is normally achieved by including mitigation measures in the requests for bids and resulting construction contracts, posting bonds, drawing up legal agreements, or recording conditions of approval on property titles or in agency permits. None of the proposed mitigation measures include any legally binding commitments or methods to ensure implementation and enforcement.

The study area is classified as nonattainment for three National Ambient Air Quality Standards ("NAAQS"): ozone, CO, and PM10. Further, the study area is classified by EPA as "extreme" nonattainment for ozone under the Federal Clean Air Act. Because of the air basin's nonattainment status, it is particularly important to reduce emissions of these nonattainment pollutants to the greatest extent feasible. The Draft EIS/EIR and the Supplement do not reduce operational or construction emissions to the greatest extent feasible.

V.A Mitigation Measures Are Not Enforceable

In our previous comments on the Draft EIS/EIR, we pointed out that several of the proposed mitigation measures were not enforceable. The same comment is valid for the numerous additional mitigation measures proposed by the Supplement.

First, many measures do not include specific performance standards that would allow these measures to be implemented, let alone allow their effectiveness to be evaluated. Three of the proposed operational mitigation measures would only "encourage" or "promote" participation, *viz.*, the LAWA telecommuting program, the LAWA carpool and rideshare program, and the promotion of alternative-fueled vehicles or SULEV/ZEV engines in commercial and rental vehicles.

Second, none of the proposed measures quantify the number of units that would be involved, the time frame over which the action would occur, nor describe the proposed measure with enough specificity to allow it to be implemented, let alone reviewed by the public or enforced if eventually adopted. The measures only require generic "acceleration," "promotion," "conversion," and "implementation." For example, the first operational measure proposes the conversion of GSE to electric power. The comment associated with this measure requires LAWA to [a]ccelerate full conversion, beyond the requirements of the GSE MOU" and to "provide incentives or tenant lease requirements." The range of potential emission reductions assumed for this measure is considerable yet the

Supplement fails to describe what kind of incentives or requirements should bring about these reductions that are not already included in CARB's GSE MOU, nor in what timeframe these incentives are supposed to be implemented, or what the term "acceleration" constitutes. (See Comment V.D.)

To be enforceable, the mitigation measures must be quantifiable. Thus, the description of a measure must specifically state what the performance goal is, when it would be provided, and how compliance would be verified.

V.B The Proposed Construction Mitigation Is Inadequate

The construction mitigation program has been expanded to include 18 mitigation measures. (Supplement, Table S4.6-18.) However, many of the measures that are listed are too general to review, let alone implement. Further, many of them are not enforceable as a practical matter as the measures as drafted do not include any emission reduction targets or any means of assuring compliance. Some of the more egregious examples are discussed below. However, all of the measures listed in the Supplement should be expanded to include emission reduction targets that can be quantified, compliance procedures, and recordkeeping and reporting provisions.

V.B.1 Construction Equipment Controls

The first listed construction mitigation measure in Table S4.6-18 would "[s]pecify combination of construction equipment using "cleaner burning diesel fuel" and exhaust emission controls." The comments to the table indicate that these mitigation measure "[o]ptions include: diesel engines with catalytic oxidizers (CO, VOC), diesel engines with particulate traps (PM), diesel engines with particulate traps (PM), diesel engines with exhaust gas circulation (NOx), diesel engine with Lubrizol fuel + catalytic oxidizer (PM, CO, VOC, NOx)."

This description is too general to evaluate. The construction activity data for Alternatives A through C in the Draft EIS/EIR in TR4 and for Alternative D in the Supplement, TRS-4 indicate that a large number of different types of equipment will be used. Efficacy of this mitigation measure and emission reductions that it can achieve can only be determined if one knows which specific measures from this list will actually be applied to which pieces of equipment in each alternative.

Clearly, the preparers of the Supplement made assumptions as to the particular mix of these controls that would be implemented for each option and control efficiencies for each in order to calculate emission reductions. The public cannot comment on the adequacy or efficacy of this measure without knowing

what particular mix of controls was assumed to derive the claimed emission reductions. Further, this measure cannot be implemented unless the specific mix of controls is clearly specified. The place to do this is in the Supplement. The total emission reductions for the entire construction mitigation program suggests that limited use is made of many of these options, while unrealistic control assumptions are made for others. (See Comment III.D.)

V.B.2 Generators

The second listed construction mitigation measure in Table S4.6-18 would “[s]pecify combination of electricity from power poles and portable diesel- or gasoline-fueled generators using ‘cleaner burning diesel’ fuel and exhaust emission controls.” The measure does not divulge the assumed mix of electric and diesel-fueled generators, specify any emission targets for the “cleaner burning diesel” fuel, identify the exhaust emission controls that would be used, or divulge the assumed emission reductions for the exhaust emission controls. Thus, the measure is not enforceable as a practical matter and cannot be reviewed by the public.

V.B.3 Off-Peak Hours

The third listed construction mitigation measure in Table S4.6-18 requires construction employees to “work” during off-peak hours. However, it is not clear what is meant by “off-peak hours.” This term is generally applied to traffic and emissions therefrom, not on-site construction “work” per se. Thus, this measure should be reworded to identify the peak hours and to require that construction workers travel to and from the site during off-peak traffic hours. If another meaning is intended, the measure should be expanded to clarify the intent and define “off-peak hours.”

V.A.4 Use Of Non-toxic Soil Stabilizers

The fourth and fifth listed construction mitigation measures in Table S4.6-18 require the use of non-toxic soil stabilizers in all inactive construction areas and on outdoor storage piles, respectively. (Supplement, p. 4-390.) A note to the table referring to these measures indicates that reductions in particulate emissions can be 90% to 95%. (Supplement, p. 4-392, note 4.) A comment applicable to this measure further states that an “[e]mission reduction credit for this measure would only account for control efficiency beyond that provided by watering required by SCAQMD Rule 403.” (Supplement, Table S4.6-18, p. 4-390, Comments column.)

However, the Supplement does not state what control efficiency was actually assumed in estimating emission reductions from this measure. It also does not state what baseline control efficiency was assumed from implementing SQAMD Rule 403. It further fails to mention to which portion of the construction emissions the emissions reduction is applied. Thus, it is impossible to evaluate the efficacy of this measure. The specific control efficiency assumed in the emission reduction calculations should be stated and required as part of the mitigation measure.

We note that 90% to 95% control for this measure is high and if assumed in the emission reduction calculations, reductions have been overestimated and actual air quality impacts understated. The SCAQMD CEQA Guidelines, for example, report a control range for the use of non-toxic soil stabilizers on inactive areas of 30 to 65% and on exposed storage piles with greater than 5% silt content of 30 to 74%. (SCAQMD 4/93, Table 11-4.)

V.B.5 SCAQMD Rule 403 Measures

The Project would qualify as a “large operation” under SCAQMD’s Rule 403. The requirements for large operations include implementation of mitigation measures in SQAMD Rule 403 Tables 1 and 2 for each source of fugitive dust *or* obtaining an approved fugitive dust emissions control plan. (SQAMD Rule 403(f).) The mitigation measures listed in the Supplement do not include obtaining a SQAMD Rule 403 Control Plan. Further, even if they did, the measures included in this plan should be set out in the Supplement for public review.

Two of the measures listed as mitigation measures in Supplement Table S4.6-18 are listed in SCAQMD Rule 403 Tables 1 and 2 and thus are regulatory requirements and cannot be treated as mitigation measures – applying dust suppression in sufficient quantity and frequency to maintain a stabilized surface to disturbed areas and active storage piles. These measures are comparable to SCAQMD Rule 403 measures 2a, 2b, and 2c in Table 2. Thus, they are not valid mitigation, but part of the baseline. We previously commented that SCAQMD Rule 403 requires implementation of best available dust suppression control measures and that soil stabilization and watering cannot be claimed as mitigation. (2001 Fox Comments, IV.A, pp. 21/22.) In response, the Supplement removed watering from the list of proposed mitigation measures but inexplicably left soil stabilization of inactive construction areas and of storage piles listed as mitigation measures. (Supplement, Appx. S-E, p. 2 and Supplement, p. 4-390.)

Further, SCAQMD Rule 403 requires certain additional mitigation that is not listed in Table S4.6-18 and was not mentioned as included in the unmitigated baseline calculations. These include the trackout provision of SCAQMD Rule 403(d)(5) and the best available control measures for high wind conditions in SCAQMD Rule 403, Table 1. The Supplement must be revised to clarify and documentation of the assumptions underlying the unmitigated baseline as well as the mitigated scenarios.

V.C All Feasible Construction Mitigation Not Required

The Supplement indicates that the revised mitigated construction emissions are significant for all alternatives and all pollutants in the interim year and in 2015, except for sulfur dioxide ("SO₂") in the interim year for Alternative D and SO₂ for all alternatives in 2015. (Supplement, Tables S4.6-23, S4.6-25.) The Supplement also indicates that these construction emissions would variously cause or contribute to violations of ambient air quality standards on CO, NO₂, and PM₁₀ in the interim and horizon year. (Supplement, Table S4.6-22.) Therefore, all feasible construction mitigation must be required for all pollutants. The Supplement has not required all feasible construction mitigation.

Mitigated construction emissions are substantially higher than significance thresholds, running into many hundreds of tons (for VOC, SO_x, PM₁₀) to many thousands of tons per year (NO_x) of pollutants. (Supplement, Table S4.6-21.) In spite of these huge emissions and the severe ozone and PM₁₀ nonattainment problems in the South Coast, this Project is proposing to mitigate only a small fraction of its emissions. The Supplement indicates that the proposed construction mitigation would reduce CO emissions by 2% to 3%; VOC emissions by 2% to 6%; NO_x emissions by 22%; SO_x emissions by 3%; and PM₁₀ emissions by 31%.²⁵ As discussed in Comment III.D.1, the claimed NO_x and PM₁₀ reductions appear to be unrealistic, given the proposed mitigation program.

These construction emissions for the Project are not included in the current State Implementation Plan ("SIP") and thus have not been considered by SCAQMD in its efforts to come into compliance with ambient air quality standards. (Draft EIS/EIR, pp. 4-476/478.) Because the South Coast is required by law to come into compliance with federal and state ambient air quality standards, these emissions must be reduced by somebody. Therefore, the Supplement by failing to propose adequate mitigation, in effect, has placed the burden on other parties to mitigate emissions from the expansion of LAX.

²⁵ Percentage reductions in emissions estimated from [(Table S4.6-21 emissions) - (Table S4.6-11 emissions)] / (Table S4.6-11 emissions).

We listed a large number of feasible construction mitigation measures in our comments on the Draft EIS/EIR. (2001 Fox Comments, IV.E, pp. 24-31.) Some of these were incorporated into the Supplement. However, many were not. The Supplement contains no explanation for its particular choice of construction mitigation measures from the list we proposed. Since our previous comments, a number of additional construction mitigation measures have been suggested and become feasible. Thus, we recommend that the Supplement be revised to require the additional feasible mitigation measures identified below. If these measures are not adopted, the Final EIS/EIR should explain with specificity why these measures are not feasible for this Project.

V.C.1 Fugitive Dust Mitigation Measures

The identification of the type and amount of construction mitigation for PM10 requires that the source of the emissions be separately calculated. However, the Supplement (and the Draft EIS/EIR) aggregate construction emissions, precluding meaningful analysis and evaluation. Thus, it is not possible to determine the amount of the total PM10 emissions that originate from fugitive dust sources (*e.g.*, wind blown dust, drop operations, earth moving) and the amount that originates from equipment exhaust. Hence, it is not possible to determine the amount of fugitive dust mitigation versus engine exhaust mitigation that is required.

However, typically, 80% to 90% of the PM10 emissions from a construction Project originate from fugitive sources. Thus, fugitive PM10 emissions remain highly significant after imposition of the mitigation measures in the Supplement. (Supplement, Table S4.6-21.) There are numerous additional feasible mitigation measures that should be required. We believe the implementation of the following measures could significantly reduce fugitive dust PM10 emissions and they should be required as mitigation for this project:²⁶

²⁶ The following acronyms are used in this listing of mitigation measures: ADEQ = Arizona Department of Environmental Quality; BCAQMD = Butte County Air Quality Management District; BAAQMD = Bay Area Air Quality Management District; CCHD = Clark County (Nevada) Health Department; MBUAPCD = Monterey Bay Unified Air Pollution Control District; SBCAPCD = Santa Barbara County Air Pollution Control District; SCAQMD = South Coast Air Quality Management District; SJVUAPCD = San Joaquin Valley Unified Air Pollution Control District; SLOCAPCD = San Luis Obispo County Air Pollution Control District; VCAPCD = Ventura County Air Pollution Control District. The mitigation measures from air pollution control agencies are taken from their respective CEQA guidelines. The references to these guidelines were provided in our previous comments. (*See* 2001 Fox Comments, IV.E.1, pp. 25 *ff.*)

- For backfilling during earthmoving operations, water backfill material or apply dust palliative to maintain material moisture or to form crust when not actively handling; cover or enclose backfill material when not actively handling; mix backfill soil with water prior to moving; dedicate water truck or large hose to backfilling equipment and apply water as needed; water to form crust on soil immediately following backfilling; and empty loader bucket slowly; minimize drop height from loader bucket. (CCHD)²⁷
- During clearing and grubbing, prewet surface soils where equipment will be operated; for areas without continuing construction, maintain live perennial vegetation and desert pavement; stabilize surface soil with dust palliative unless immediate construction is to continue; and use water or dust palliative to form crust on soil immediately following clearing/grubbing. (CCHD)
- While clearing forms, use single stage pours where allowed; use water spray to clear forms; use sweeping and water spray to clear forms; use industrial shop vacuum to clear forms; and avoid use of high pressure air to blow soil and debris from the form. (CCHD)
- During cut and fill activities, prewater with sprinklers or wobblers to allow time for penetration; prewater with water trucks or water pulls to allow time for penetration; dig a test hole to depth of cut to determine if soils are moist at depth and continue to prewater if not moist to depth of cut; use water truck/pull to water soils to depth of cut prior to subsequent cuts; and apply water or dust palliative to form crust on soil following fill and compaction. (CCHD)
- For large tracts of disturbed land, prevent access by fencing, ditches, vegetation, berms, or other barrier; install perimeter wind barriers 3 to 5 feet high with low porosity; plant perimeter vegetation early; and for long-term stabilization, stabilize disturbed soil with dust palliative or vegetation or pave or apply surface rock. (CCHD)
- In staging areas, limit size of area; apply water to surface soils where support equipment and vehicles are operated; limit vehicle speeds to 15 mph; and limit ingress and egress points. (CCHD)
- For stockpiles, maintain at optimum moisture content; remove material from downwind side; avoid steep sides or faces; and stabilize material following stockpile-related activity. (CCHD)

²⁷ Clark County [Nevada] District Board of Health, Construction Activities Notebook Including the Section 94 Handbook, August 24, 2000.

- To prevent trackout, pave construction roadways as early as possible; install gravel pads; install wheel shakers or wheel washers, and limit site access. (CCHD)
- When materials are transported off-site, all material shall be covered, effectively wetted to limit visible dust emissions, or at least six inches of freeboard space from the top of the container shall be maintained (BAAQMD, SJVUAPCD, SCAQMD Rule 403 Handbook,²⁸ ADEQ²⁹).
- Trucks transporting fill material to and from the site shall be tarped from the point of origin. (SBCAPCD, SCAQMD Rule 403 Handbook)
- Where feasible, use bedliners in bottom-dumping haul vehicles. (SCAQMD Rule 403 Handbook)
- Install wind breaks at windward side(s) of construction areas (BAAQMD, SJVUAPCD).
- Grade each phase separately, timed to coincide with construction phase or grade entire project, but apply chemical stabilizers or ground cover to graded areas where construction phase begins more than 60 days after grading phase ends (SCAQMD Rule 403 Handbook).
- All operations shall limit or expeditiously remove the accumulation of mud or dirt from adjacent public streets at least once every 24 hours when operations are occurring. (BAAQMD) The SJVUAPCD adds: The use of dry rotary brushes is expressly prohibited except where preceded or accompanied by sufficient wetting to limit the visible dust emissions. Use of blower devices is expressly forbidden. (SJVUAPCD).
- Cover inactive storage piles. (BAAQMD, BCAQMD, SBCAPCD, MBUAPCD)
- Cover active storage piles. (SCAQMD Rule 403 Handbook)
- Install sandbags or other erosion control measures to prevent silt runoff to public roadways from sites with a slope greater than 1% (BAAQMD, SJVUAPCD).
- Limit areas subject to excavation, grading, and other construction activity at any one time (BAAQMD, SJVUAPCD).

²⁸ South Coast Air Quality Management District (SCAQMD), Rule 403 Implementation Handbook, January 1999.

²⁹ Arizona Department of Environmental Quality ("ADEQ"), Air Quality Exceptional and Natural Events Policy PM10 Best Available Control Measures, June 5, 2001.

- During initial grading, earth moving, or site preparation, projects 5 acres or greater may be required to construct a paved (or dust palliative treated) apron, at least 100 ft in length, onto the project site from the adjacent site if applicable. (BCAQMD)
- Replant vegetation in disturbed areas as quickly as possible. (BAAQMD)
- Gravel pads must be installed at all access points to prevent tracking of mud on to public roads. (SBCAPCD)
- The contractor or builder shall designate a person or persons to monitor the dust control program and to order increased watering, as necessary, to prevent transport of dust offsite. (SBCAPCD, SLOCAPCD)
- Prior to land use clearance, the applicant shall include, as a note on a separate informational sheet to be recorded with map, these dust control requirements. All requirements shall be shown on grading and building plans. (SBCAPCD, SLOCAPCD)
- Use 3- to 5-foot barriers with 50% or less porosity located adjacent to roadways or urban areas to reduce windblown material leaving site (SCAQMD Rule 403 Handbook).
- Barriers with 50% or less porosity located adjacent to roadways to reduce windblown material leaving a site. (SCAQMD Rule 403 Handbook)
- During high wind conditions, cease all land clearing and earth moving operations or apply water within 15 minutes to any soil surface that is being moved or otherwise disturbed. (SCAQMD Rule 403 Handbook, CCHD)
- Limit fugitive dust sources to 20% opacity. (ADEQ)
- Require a dust control plan for earthmoving operations. (ADEQ)
- Limit speed on unpaved roads. (SCAQMD, ADEQ)
- All demolition materials shall be wet crushed. (El Toro FEIR)³⁰
- Increase watering from twice a day to four times daily during initial storage pile placement and maximize application of non-toxic soil binders according to manufacturer's specification to exposed stock

³⁰ County of Orange, Final Environmental Impact Report No. 573 for the Civilian Reuse of MCAS El Toro and the Airport System Master Plan for John Wayne Airport and Proposed Orange County International Airport, SCH No. 98101053, August 2001.

piles (*i.e.* gravel, sand, dirt) with 5% or greater silt content. (El Toro FEIR)

- All grading equipment will be mounted with TrueFog dust suppression technology or comparable technology. This technology sprays a very fine mist of water around the construction equipment. This combines with the fugitive dust in the air causing it to fall back to the ground. (El Toro FEIR)
- All locations where scrapers, dozers and compactors will be traveling on exposed earth shall be watered four times per day and soil binders shall be used daily as necessary, consistent with manufacturers' directions. (El Toro FEIR)
- All demolition materials shall be wet crushed. (El Toro FEIR)

These measures have been widely used and required as CEQA mitigation in numerous EIRs. See, for example, the fugitive dust control program for the Big Dig (Kasprak and Stakutis 2000³¹), for the El Toro Reuse Final EIR, and for the Padres Ballpark Final EIR³².

V.C.2 Construction Exhaust Mitigation Measures.

The CO, VOC, NO_x, and SO_x construction emissions originate solely from the combustion of fuel in engines of construction equipment. About 10% to 20% of the PM₁₀ emissions also originate from engine exhaust. The mitigated construction emissions as disclosed in the Supplement and Draft EIS/EIR exceed the significance thresholds by substantial amounts in all years and for all alternatives for CO, VOC, and NO_x and in 2004 for alternatives A through C. Nonetheless, the Supplement only proposes three measures with the potential to significantly reduce these emissions – the use of “cleaner burning fuels,” the use of post-combustion controls and/or exhaust gas recirculation, and the use of electricity from power poles, where available. However, the emission reductions assumed in the mitigated air quality analyses suggest that these measures would not be used to the extent feasible. (*See* Comment III.D.) Further, there are

³¹ A. Kasprak and P.A. Stakutis, A Comprehensive Air Quality Control Program for a Large Roadway Tunnel Project, Proceedings of the Air & Waste Management Association's 93rd Annual Conference 7 Exhibition, June 18-22, 2000.

³² City of San Diego, Final Subsequent Environmental Impact Report to the Final Master Environmental Impact Report for the Centre City Redevelopment Project and Addressing the Centre City Community Plan and Related Documents for the Proposed Ballpark and Ancillary Development Projects, and Associated Plan Amendments, V. IV. Responses to Comments, September 13, 1999, pp. IV-254 to IV-256.

additional feasible mitigation measures that could be implemented to further reduce exhaust emissions. These include:

- Configure construction parking to minimize traffic interference. (SCAQMD)
- Provide temporary traffic control during all phase of construction activities to improve traffic flow (*e.g.*, flagperson). (SCAQMD)
- Develop a construction management plan that includes but is not limited to rerouting construction of congested streets, consolidating truck deliveries, providing dedicated turn lanes for movement of construction trucks and equipment on-site and off-site, and minimizing use of construction vehicles and equipment. (SCAQMD)
- Use alternative fueled (*e.g.*, LNG, natural gas) construction equipment. (SJVUAPCD)
- Limit the idling time to 2 minutes (SCAQMD), instead of the proposed 10 minutes.
- Limit the hours of operation of heavy duty equipment and/or the amount of equipment in use. (SJVUAPCD)
- Implement activity management (*e.g.*, rescheduling activities to reduce short-term impacts). (SJVUAPCD)
- Construction equipment operating onsite shall be equipped with two to four degree engine timing retard or pre-combustion chamber engines. (SBCAPCD, SLOCAPCD)
- Install high pressure injectors on diesel construction equipment. (SLOCAPCD)
- Install catalytic converters on gasoline-powered equipment, where feasible. (SBCAPCD, SLOCAPCD)
- Minimize construction worker trips by requiring carpooling or use of public transit. (SBCAPCD)
- During smog season (May through October), the construction period should be lengthened so as to minimize the number of vehicles and equipment operating at the same time. (VCAPCD)
- Construction would take place over an extended period of time, from 2004 through 2015. Thus, require the use of new technologies to control emissions as they become available and feasible. (VCAPCD)

- Require the use of catalytic oxidizers and particulate traps on all equipment where feasible, rather than the rather low percentage usage assumed in the Supplement. *See* Comment III.D.
- Require the recalibration (reflash) of engine software on applicable 1993 to 1998 electronically controlled engines to reduce NOx emissions.
- Require the use of ultra-low sulfur diesel (5 to 15 ppmw) in all diesel-fueled on-site construction equipment and all delivery trucks.
- If PuriNOx™ or equivalent diesel formulation is used, require that it be formulated from ultra-low sulfur diesel.
- Replace fuel injectors.
- Use closed loop crankcase filtration.
- Use lean NOx catalysts (MECA)
- Use enhanced combustion modifications, *e.g.*, cams, coating, supercharger, engine rebuild kits (MECA)
- Use selective catalytic reduction ("SCR") and oxidation system combinations on construction equipment to control PM (20-50% reduction, CO and VOCs (up to 90% reduction), and NOx (50-90%) reduction. (MECA)
- For all emissions above the significance thresholds not otherwise reduced, require emission offsets. (SLOCAPCD).
- All off-road construction equipment shall comply with the requirements of 40 CFR (9, 86, 89) Tier 2 emission requirements, which provide for strict emission limits for construction vehicles. (El Toro FEIR)
- All off-road construction equipment shall comply with the requirements of AQMP Measures M9 and M10, limiting NOx emissions to 2.5 g/bhp-hr, beginning the first day of construction. (El Toro FEIR.)
- Set CO, VOC, NOx, PM10, and SOx emission reduction goals for the construction fleet that require a minimum overall 80% reduction in emissions.
- All on-site mechanic and foreman trucks and vehicles will be required to meet Super Ultra-low Emission Vehicle ("SULEV") or Zero Emission Vehicle ("ZEV") emission standards. (El Toro FEIR)
- To the maximum extent permitted by law and regulations, the County and its contractors shall require that construction workers be housed

(Monday through Friday) on-site in trailers/mobile homes/RVs or reused military housing, and shall provide rail/bus/metro passes or clean vehicle shuttle service for those construction workers that will not be housed on-site. (El Toro FEIR)

- LAWA and its contractors shall provide clean-fleet shuttles to major transit stations and multi-modal centers during construction phases of the Project.
- The construction contractors shall use emulsified asphalts that do not contain volatile hydrocarbons in lieu of cutback asphalts to avoid VOC emissions associated with cutback asphalts. (El Toro FEIR)
- The amount of architectural coatings shall be minimized by using spray equipment that has high transfer efficiencies, such as the electrostatic spray gun and manual paint applicators. (El Toro FEIR)
- Pre-coated materials or materials that have natural surfaces shall be used to the maximum extent feasible to avoid the use of VOC emissions from architectural coatings. The building surface areas used for the project shall be at least 70 percent precoated or composed of natural surfaces. (El Toro FEIR)
- The county shall use low or zero VOC content paints wherever feasible to reduce VOC emissions from architectural coatings. (El Toro FEIR)

These measures have been widely used and required as CEQA mitigation in numerous EIRs. *See*, for example, the exhaust emissions reduction program for the El Toro Reuse Final EIR.

V.D Operational Mitigation Measures Are Inadequate

The operational mitigation program has also been revised and now includes 19 mitigation measures. (Supplement, Table S4.6-18.) Again, many of the proposed measures are too general to review or implement because they do not include any emission reduction targets, timeline for their implementation, or any means of assuring compliance. (*See* Comment V.A.)

As discussed earlier, the Supplement's analyses of operational emissions and resulting projected ambient air quality concentrations are seriously flawed. (*See* Comment IV.) However, even with the Supplement's flawed results, mitigated PM10 air quality impacts remain significant for all alternatives in both the interim year and in the year 2015. Consequently, all feasible mitigation must be implemented.

In our previous comments on the Draft EIS/EIR, we recommended a number of additional feasible mitigation measures, such as reduction of existing sources at LAX, reducing emissions from sources outside of LAX, and offsetting emissions with Reclaim credits. (2001 Fox Comment, IV.F.) The Supplement ignored most of these recommendations. Because air quality impacts remain significant after mitigation, LAWA must adopt all feasible mitigation.

V.D.1 Heat Island Effect And Energy Conservation Not Adequately Addressed

We previously commented on the fact that the Draft EIS/EIR ignored the urban heat island effect generated by the hot surfaces of dark pavements and roofs in its air quality analysis, and recommended the implementation of mitigation that requires the use of “cool surfaces” for paving and roofs. (2001 Fox Comments, III.E, p. 20.) We further commented on the lack of commitment to the measures described in the Master Plan’s energy conservation and efficiency program, the absence of specific measures and performance goals, and the fact that the plan is not applicable to existing structures. We recommended a long list of potential mitigation measures to address these issues, including the use of energy star roof products, energy-efficient air conditioners (*e.g.*, water-cooled, rather than air-cooled), high-efficiency lighting and glass, daylighting (*e.g.*, skylights), high-efficiency motors, automatic controls for lighting and equipment, photocell dimming, higher insulation levels than required by code, reflective roofs, and photovoltaics, among others. (2001 Fox Comments, IV.G, pp. 33 *ff.*)

The Supplement addressed our comments by including a single mitigation measure that appears to combine these issues, the “Energy Conservation” measure, which proposes to “[c]over any parking structures that receive direct sunlight to reduce volatile emissions from vehicle gasoline tanks and install solar panels on these roofs where feasible to supply electricity or hot water.” It adds that this measure would “potentially apply to surface lots and the top deck of parking garages” and that “[i]n installation of solar panels may only be feasible in decentralized structures.” (Supplement, p. 4-391.)

This measure does not contain a commitment to implement this measure, as it is only “potentially” applicable and “may only be feasible in decentralized structures.” In addition, the measure as drafted would apply only to parking structures and only marginally reduce the heat island effect by reducing VOC emissions from vehicle gasoline tanks. The Supplement does not provide an explanation how it intends to further address the heat island effect. It does not commit to installing “cool surfaces” on either the parking structures or any buildings. The use of solar panels on the numerous airport buildings was also

not required and there is no explanation of why none of the many other proposed energy conservation measures were adopted. Clearly, this measure is window-dressing at best and does not adequately address LAWA's obligation to implement energy conservation and efficiency measures to mitigate the significant impacts from its operation.

V.D.2 Establishment Of ITCs Not Valid Mitigation

The Supplement claims that substantial emission reductions can be achieved through the construction of five additional intermodal transportation centers ("ITCs"), so-called "flyaways." As discussed above in Comment IV.B above, only one such ITC is proposed in Alternative D and none for Alternatives A through C. Consequently, the potential emissions reductions need to be reduced to a fifth of their present values for the calculation of mitigated emissions from Alternative D. No emission reduction credits for ITCs can be applied to Alternatives A through C.

VI. DOCUMENTS UPDATED AFTER INITIAL PUBLICATION

The documents pertaining to the Supplement that were provided to us on a CD-ROM by LAWA are inconsistent with the documents presented on LAWA's LAX Master Plan internet homepage³³. For example, Attachments I and N to the Technical Report S-4, Air Quality, contained only headers on otherwise empty pages in the CD-ROM copy we were provided with. The document provided on the internet on the other hand contains complete tables with data. We have not been notified by LAWA that changes were made to the Supplement and its associated documents. The LAWA Master Plan homepage itself also does not contain any notification that documents have been updated nor do the documents themselves contain any note to alert the reader to the fact.

We were unable to verify whether the content of other documents had also been updated or changed from the version we were provided with by LAWA. LAWA and FAA have a legal obligation under CEQA and NEPA to make their environmental analysis readily accessible to the public. This was a problem with the publication of the Draft EIS/EIR as well as the Supplement. The publication of inconsistent, incomplete, and altered documents in different locations fails to satisfy the agencies' legal obligation, renders the documents confusing and difficult to understand, and requires an explanation of the discrepancies and publication of corrected documents.

³³ LAX Master Plan, <http://www.laxmasterplan.org>, accessed October 29, 2003.

HUMAN HEALTH AND SAFETY

VII. PUBLIC HEALTH IMPACTS ARE UNDERESTIMATED

We previously commented on the serious inadequacy of the Draft EIS/EIR's human health risk assessment ("HHRA"), which resulted from the use of inappropriate thresholds of significance, the lack of an assessment of non-cancer acute health risks, the underestimation of acrolein chronic health impacts, the inadequate assessment of lead, the lack of an assessment of health impacts from construction emissions, the inappropriate use of high instead of low load factors to estimate aircraft engine emissions, the lack of an assessment of health risk to terminal passengers, and the lack of a cumulative health risk assessment. Further, the proposed mitigation program, identical to the air quality mitigation program discussed in Comment IV, is inadequate for human health impacts for the same reasons discussed above. Additionally, the proposed mitigation program fails to recognize the differences in approaches that are required to mitigate air quality versus human health impacts. (2001 Fox Comments, V., pp. 40 *ff.*)

The Supplement addressed only a few of these issues. Consequently, our previous comments remain applicable, and are applicable to the evaluation of Alternative D as well. In addition, the Supplement has introduced some new problems, which are discussed below.

VII.A Health Risk Assessment Is Inadequate

The conclusions drawn in the Supplement's HHRA regarding the — mostly insignificant — impacts of proposed expansions of LAX, particularly with respect to Alternative D, are questionable. Neither the Draft EIS/EIR, nor the Supplement or their associated technical reports provide detailed enough information to comprehend or reproduce the steps taken in the HHRA to estimate acute and chronic noncancer health risks and cancer health risks from Project emissions. However, there are a number of indications that the HHRA is substantially flawed.

The methodology and data sets used by both the Draft EIS/EIR and Supplement results in substantial underestimates of the toxic air pollutant ("TAP") emissions inventories for the Project. This, in turn, results in considerable underestimates of ambient air TAP concentrations and, consequently, in erroneous conclusions regarding the significance of Project impacts. A number of reasons contribute to this substantial underestimate, as discussed in the following.

VII.A.1 TAP Emissions Estimates Unsupported

A HHRA, *i.e.* the assessment of acute and chronic noncancer health risks and cancer health risks, relies on modeled ambient air TAP concentrations due to a project, which are based on an accurate emissions inventory for TAPs. The Supplement, following the Draft EIS/EIR's general approach and methodology, follows the standard approach to estimate emissions of TAPs from mobile and stationary sources, calculated by multiplying the VOC or PM emissions by the percent mass composition of the exhaust gas, called a speciation profile: "[t]he toxic air pollutant emissions will be calculated by multiplying the appropriate criteria pollutant (VOC or particulate matter) emissions by the relative toxic pollutant emission factor." (Supplement, p. 4-616 and Draft EIS/EIR, TR14a, Attachment B, p. 10.)

The Draft EIS/EIR's Technical Report 14a³⁴ ("TR14a"), Attachment F, Air Quality Modeling Protocol for Toxic Air Pollutants, asserts that "[a]ll such references will be discussed and emission factors justified. In cases where different emission factors in different reference documents are found for the same emission source, the reference most appropriate for operations in Southern California will be used." (TR14a, Attachment F, p. 2.)

However, beyond disclosure of names of the databases used to determine TAP emission factors, neither the Draft EIS/EIR nor the Supplement or their associated technical reports and attachments contain a summary of those "relative toxic pollutant emission factors" that were selected to estimate TAP emissions from the myriad of stationary and mobile sources at LAX. The Supplement does not disclose which emission factors were chosen from which database for which source nor does it provide a justification for the selected factor.

Without this information it is impossible to verify whether the Draft EIS/EIR or the Supplement selected appropriate emission factors for the various sources. Further, other pertinent information in the Supplement is missing. For example, the associated Technical Report 9a³⁵ ("TR9a"), Attachment A, Risk Calculations for Maximally Exposed Resident and Child, only contains a header on an otherwise empty page. Thus it impossible to verify the Supplement's calculations of TAP emissions resulting from the Project alternatives, the

³⁴ LAX Master Plan Draft Environmental Impact Statement/Environmental Impact Report, Technical Report 14a: Human Health Risk Assessment, January 2001.

³⁵ LAX Master Plan Supplement to the Draft Environmental Impact Statement/Environmental Impact Report, Technical Report 9a: Supplemental Human Health Risk Assessment, June 2003.

incremental ambient air TAP concentrations, and in turn their associated health risks.

VII.A.2 TAP Emission Factors Are Inadequate

It appears that the Supplement relied on the same outdated sources listed in the Draft EIS/EIR for determining the TAP emission factors. The Supplement does not contain any indication that it used updated versions for any of these sources. The reader must therefore assume that the sources for speciation profiles or TAP emission factors are the same as those used in the Draft EIS/EIR. The Draft EIS/EIR's TR14a, Attachment B, Screening Level Human Health Risk Assessment, specifies that "TAP emissions were estimated using VOC and PM emission estimates and combined with speciation data from SPECIATE, FIRE, and XATEF, and USEPA Guidance on Mobile Source HAPs." (Draft EIS/EIR, TR14a, Attachment B, p. 14.)

Inspection of the respective references reveals that the Draft EIS/EIR used the 1993 version of FIRE and SPECIATE, and the 1992 version of XATEF to determine TAP emission factors. (Draft EIS/EIR, TR14a, Attachment B, p. 14.) The XATEF database has long been retired by U.S. EPA and some of its emission factors incorporated in its FIRE database.³⁶ The latest version of FIRE, version 6.23, was released in October, 2000, and, thus, would have been available for the Supplement's HHRA. The U.S. EPA's SPECIATE database has also been updated several times and is currently available as version 3.2. Release notes to the preceding version, released in October 1999 and thus available to both the Draft EIS/EIR and Supplement, state that "SPECIATE v3.0 contains 262 new TOC profiles and 13 new PM profiles."³⁷

While the Draft EIS/EIR claims that "[t]he HHRA used well-accepted methods and best available emission factor data to develop estimates of emissions, and estimates and assumptions are reasonable and appropriate," this is clearly not the case. (Draft EIS/EIR, p. 76.) The HHRA must be revised using the most recent available TAP speciation profiles or emission factors.

³⁷ United States Environmental Protection Agency, Technology Transfer Network, Clearinghouse for Inventories & Emission Factors, SPECIATE Version 3.2; http://www.epa.gov/ttn/chief/software/speciate/spec32_rel_notes.txt, accessed November 3, 2003.

VII.A.3 TAP Emissions Are Underestimated

The Supplement's TAP emission estimates are based on emissions of VOCs and PM from mobile and stationary sources, calculated by multiplying the VOC or PM emissions by the TAP relative emission factor. As discussed above in the air quality section of this comment letter, the Supplement has substantially underestimated unmitigated VOC and PM emissions from the Project and substantially overestimated the control efficiency of its proposed mitigation program. Consequently, the estimated mitigated emissions from the Project are grossly underestimated and should be revised. Consequently, TAP emissions that are based on these underestimated VOC and PM emissions are also substantially underestimated.

The Supplement concludes that most health risks for Alternative D would be lower in both the interim year and the horizon year 2015 than they would be if no Master Plan improvements were undertaken, *i.e.* the NA/NP alternative. These conclusions are unsupported. We expect that an HHRA that evaluates TAP impacts from the Project based on current TAP relative emission factors and accurate estimates of air pollutant emissions will be significant for all alternatives including Alternative D. The HHRA must be revised and the Draft EIS/EIR recirculated for public review.

VII.B Significance Thresholds

VII.B.1 Chronic Hazard Index

We previously commented on the Draft EIS/EIR's inappropriate and unsupported significance thresholds for the incremental hazard index used in the HHRA to evaluate chronic and acute noncancer health impacts. (2001 Fox Comments, V.A, p. 41). The Draft EIS/EIR used a total incremental hazard index of "greater than 5 for any target organ system at any receptor location" as the significance threshold for both noncancer chronic and acute health impacts. (Draft EIS/EIR, p. 4-1009.)

We commented that the appropriate significance threshold for both the chronic and acute health hazard index is 1. This threshold was established in 1993 CARB guidelines,³⁸ is routinely used in HHRAs conducted for EIRs and by every air district in the State that has established significance thresholds for noncancer health risks for purposes of CEQA. We previously provided excerpts

³⁸ California Air Resources Control Board, Risk Management Guidelines for New and Modified Sources of Toxic Pollutants, July 1993.

from CEQA guidelines as well as excerpts from EIRs prepared for other projects in the SCAQMD. (2001 Fox Comments, Ex. 2 and 3.)

In response, the Supplement appropriately reduced the significance threshold for the total incremental *acute* hazard index from 5 to 1 “to conform to SCAQMD policies.” However, the Supplement left the significance threshold for the *chronic* hazard index at 5, citing SCAQMD Rule 1402 as a reference. (Supplement, p. 4-620.) This is inappropriate. While SCAQMD Rule 1402 in fact cites a chronic hazard index of 5, it is not applicable in the instant case, as explained below. Its mere existence, thus, does not provide justification for not using the lower significance threshold of 1, which is routinely used in HHRAs and recommended by most (all?) air districts in their CEQA Guidelines as well as SCAQMD guidance.

Further, SCAQMD Rule 1402 is intended to reduce the health risk associated with “existing facilities” to implement risk reduction plans as required by the Air Toxics Information and Assessment Act, the so-called “Hot Spots Act” of 1987. LAX in its present configuration is an already existing facility and SCAQMD Rule 1402 indeed applies. However, the modernization of LAX as proposed by the Draft EIS/EIR and Supplement is further subject to SCAQMD Rule 1401³⁹, which applies to new and modified sources. Modifications are defined as “any physical change in, change in method of operation, or addition to an existing permit unit that requires an application for a permit to construct and/or operate.” (SCAQMD Rule 1401, c(9).) Clearly, the modernization of LAX classifies as a modification. SCAQMD Rule 1401 specifies a chronic hazard index of 1. Consequently, if LAWA relies on SCAQMD guidance and rules to justify its choice of a hazard index, it must take all applicable regulations into consideration and consequently set the chronic hazard index significance threshold at 1, rather than 5.

Further, the Supplement claims that its CEQA thresholds of significance are “based on recent SCAQMD policies” and are “consistent with the SCAQMD CEQA Handbook for assessing impacts of new developments as well as recent, publicly available correspondence from SCAQMD.” The SCAQMD CEQA Guidelines themselves do not contain a significance threshold for the hazard index. However, the guidelines rely on “Rule 1401, with which the project proponent must comply before the project can be constructed and put into operation.” Clearly, SCAQMD Rule 1401 would be the applicable rule that the Supplement should have consulted, not SCAQMD Rule 1402.

³⁹ South Coast Air Quality Management District, Rule 1401 – New Source Review of Toxic Air Contaminants, amended May 2, 2003.

Although SCAQMD Rule 1401 does not apply to aircraft emissions at LAX because the SCAQMD does not have jurisdiction over mobile source emissions, the choices for significance thresholds in this rule reflect the general state-wide consensus on this issue. As a practical matter, the significance of health impacts does not depend on the source of the emissions – mobile sources versus stationary sources – only on the specific chemicals and their impacts on humans. Thus, jurisdiction is irrelevant for purposes of CEQA.

CARB issued risk management guidelines in 1993 recommending an even lower significance threshold of 0.2 for the non-cancer chronic hazard index. If the index exceeds 0.2, best available control technology for toxics (“TBACT”) is required. The Bay Area Air Quality Management District (“BAAQMD”) is currently in the process of lowering its recommended threshold for requiring T-BACT to 0.2.⁴⁰

Clearly, the choice of a chronic hazard index of 5 flies in the face of every relevant regulatory guidance as well as state-wide standard practice. At a minimum, the Supplement should have chosen a hazard index of 1, if not lower. By selecting the higher significance threshold of 5, the Supplement and Draft EIS/EIR have failed to find significant impacts that should have been mitigated.

VII.B.2 Cancer Risk

The Supplement, as the previous Draft EIS/EIR, uses a significance threshold of 10 in one million for the incremental cancer risk. The Supplement does not provide a reference for this threshold beyond its claim that its CEQA thresholds of significance are “based on recent SCAQMD policies” and are “consistent with the SCAQMD CEQA Handbook for assessing impacts of new developments as well as recent, publicly available correspondence from SCAQMD.” (Supplement, p. 4-620.) The cited recent correspondence is a comment letter from SCAQMD on the El Toro DEIR.⁴¹ This comment letter refers back to the SCAQMD CEQA Guidelines as being the applicable guidance for determining the significance threshold for incremental cancer risk.

⁴⁰ Bay Area Air Quality Management District, Workshop Notice, Re: Proposed Changes To District Air Toxics New Source Review Program, May 2, 2003, <http://www.baaqmd.gov/pln/ruledev/2-5/r0205ws1.htm>, accessed November 2, 2003; and Bay Area Air Quality Management District, Draft Staff Report, Appendix D, CEQA Initial Study, April 2003.

⁴¹ South Coast Air Quality Management District, Comments of the AQMD, Draft Environmental Impact Report No. 573, Civilian Reuse of MCAS El Toro and the Airport System Master Plan for John Wayne Airport and Proposed Orange County International Airport, Letter from Steve Smith, SCAQMD, to Bryan Speegle, County of Orange, Master Development Program, February 22, 2000.

The SCAQMD CEQA Guidelines specify the significance threshold for incremental cancer risk as follows:

“Any project involving the emission or threatened emission of a carcinogenic or toxic air contaminant identified in District Rule 1401 that exceeds the maximum individual cancer risk of *one in one million* or *10 in one million if the project is constructed with best available control technology for toxics (T-BACT)* using the procedures in District Rule 1401.” [Emphasis added.]

Considering the substantial emissions of air toxics from the Project and the absence of any proposed T-BACT measures, the HHRA should have used a cancer significance threshold of one in one million.

VIII. MITIGATION OF HEALTH IMPACTS IS INADEQUATE

As we discussed in our previous comments, The Draft EIS/EIR did not impose any mitigation specifically for health impacts, instead relying exclusively on air quality mitigation. (2001 Fox Comments, VI., pp. 46/47.) The Supplement failed to propose any additional mitigation measures that would substantially reduce VOC and PM emissions, the surrogates used for estimating TAP emissions. As discussed above in Comment V, the air quality mitigation program is entirely inadequate for mitigating air quality impacts. This program is likewise inadequate to mitigate health impacts, for the same reasons discussed in Comment V. The air quality mitigation program would only marginally reduce the emissions of VOCs and PM. Thus, TAP emissions, which are based on VOC and PM emissions, would likewise be high.

Further, the proposed mitigation program fails to recognize the differences in approaches that are required to mitigate air quality versus human health impacts. It is not sufficient to rely solely on air quality mitigation to mitigate public health impacts. Other types of mitigation measures should be considered to prevent exposure and thus protect public health. These might include measures such as upgrading the LAX ventilation system, installing efficient charcoal filters on the LAX intake air to remove TAPs, and improving the ventilation systems and treating the intake air of nearby sensitive receptors who would be most affected by TAP emissions from the Project.

REPRESENTATIVE EXPERIENCE

Performed environmental investigations, as outlined below, for a wide range of industrial and commercial facilities including refineries, reformulated fuels projects, petroleum distribution terminals, conventional and thermally enhanced oil production, underground storage tanks, pipelines, gasoline stations, landfills, railyards, hazardous waste treatment facilities, power

plants, transmission lines, airports, hydrogen plants, petroleum coke calcining plants, asphalt plants, cement plants, incinerators, flares, manufacturing facilities (semiconductors, electronic assembly, aerospace components, printed circuit boards, amusement park rides), lanthanide processing plants, ammonia plants, urea plants, food processing plants, grain processing facilities, paint formulation plants, wastewater treatment plants, marine terminals, gas processing plants, steel mills, battery manufacturing plants, pesticide manufacturing and repackaging facilities, pulp and paper mills, redevelopment projects (e.g., Mission Bay, Southern Pacific Railyards, Moscone Center expansion, San Diego Padres Ballpark), residential developments, commercial office parks, campuses, and shopping centers, server farms, and a wide range of mines including sand and gravel, hard rock, limestone, nacholite, coal, molybdenum, gold, zinc, and oil shale.

EXPERT WITNESS/LITIGATION SUPPORT

- Assist citizens group and labor union challenge issuance of conditional use permit issued for at 317,000 ft² discount store in Honolulu without any environmental review. In support of a motion for preliminary injunction, prepared 7 page declaration addressing public health impacts of diesel exhaust from vehicles serving the Project. In preparation for trial, prepared 20-page preliminary expert report summarizing results of diesel exhaust and noise measurements at two big box retail stores in Honolulu, estimated diesel PM10 concentrations for Project using ISCST, prepared a cancer health risk assessment based on these analyses, and evaluated noise impacts. Case in progress.
- Assist environmental organizations to challenge the DOE Finding of No Significant Impact (FONSI) for the Baja California Power and Sempra Energy Resources Cross-Border Transmissions Lines in the U.S. and four associated power plants located in Mexico (DOE EA-1391). Prepared 20-page declaration in support of motion for summary judgement, addressing emissions, including CO₂ and NH₃, offsets, BACT, cumulative air quality impacts, alternative cooling systems, and water use and water quality impacts. Plaintiff's motion for summary judgment granted in part. U.S. District Court, Southern District decision concluded that the Environmental Assessment and FONSI violated NEPA and the APA due to their inadequate analysis of the potential controversy surrounding the project, water impacts, impacts from NH₃ and CO₂, alternatives, and cumulative impacts. Border Power Plant Working Group v. Department of Energy and Bureau of Land Management, Case No. 02-CV-513-IEG (POR) (May 2, 2003).

- Assist unions in appeal of Title V permit issued by BAAQMD to carbon plant that manufactured coke. Reviewed District files and prepared technical comments on Title V permit. Reviewed responses to comments and assisted counsel draft appeal to BAAQMD hearing board, opening brief, motion to strike, and rebuttal brief. Case settled.
- Assisted California Central Coast city obtain controls on a proposed new city that straddles the Ventura-Los Angeles County boundary. Reviewed several environmental impact reports, prepared an air quality analyses, a diesel exhaust health risk assessment, and detailed review comments.
- Assisted Central California city to obtain controls on large alluvial sand quarry and asphalt plant proposing a modernization. Prepared comments on Negative Declaration on air quality, public health, noise, and traffic. Evaluated process flow diagrams and engineering reports to determine whether proposed changes increased plant capacity or substantially modified plant operations. Prepared comments on application for categorical exemption from CEQA. Presented testimony to County Board of Supervisors. Developed controls to mitigate impacts. Assisted counsel draft Petition for Writ. Case settled June 2002. Substantial improvements in plant operations were obtained including cap on throughput, dust control measures, asphalt plant loadout enclosure, and restrictions on truck routes.
- Assisted oil companies on the California Central Coast in defending class action citizens lawsuit alleging health effects due to emissions from gas processing plant and leaking underground storage tanks. Reviewed regulatory and other files and advised counsel on merits of case. Case settled November 2001.
- Assist oil company on the California Central Coast in defending property damage claims arising out of a historic oil spill. Reviewed site investigation reports, pump tests, leachability studies, and health risk assessments, participated in design of additional site characterization studies to assess health impacts, and advised counsel on merits of case. Prepare health risk assessment.
- Assisted unions in appeal of Initial Study/Negative Declaration ("IS/ND") for an MTBE phaseout project at a Bay Area refinery. Reviewed IS/ND and supporting agency permitting files and prepared technical comments on air quality, groundwater, and public health impacts. Reviewed responses to comments and final IS/ND and ATC permits and assisted counsel to draft petitions and briefs appealing decision to Air District Hearing Board. Presented sworn direct and rebuttal testimony with cross examination on groundwater impacts of ethanol spills on hydrocarbon contamination at refinery. Hearing Board ruled 5 to 0 in favor of appellants, remanding ATC to district to prepare an EIR.
- Assist Florida cities in challenging the use of diesel and proposed BACT determinations in prevention of significant deterioration (PSD) permits issued to two 510-MW simple cycle peaking electric generating facilities and one 1,080-MW simple cycle/combined cycle facility. Reviewed permit applications, draft permits, and FDEP engineering evaluations,

assisted counsel in drafting petitions and responding to discovery. Participated in settlement discussions.

- Assisted large California city in federal lawsuit alleging peaker power plant is violating its federal permit. Reviewed permit file and applicant's engineering and cost feasibility study to reduce emissions through retrofit controls. Advised counsel on feasible and cost-effective NO_x, SO_x, and PM₁₀ controls for several 1960s diesel-fired Pratt and Whitney peaker turbines.
- Assist coalition of Georgia environmental groups in evaluating BACT determinations and permit conditions in PSD permits issued to several large natural gas-fired simple cycle and combined-cycle power plants. Prepare technical comments on draft PSD permits on BACT, enforceability of limits, and toxic emissions. Review responses to comments, advise counsel on merits of cases, participate in settlement discussions, present oral and written testimony in adjudicatory hearings, and provide technical assistance as required. Cases settled.
- Assist citizen's group in Massachusetts review, comment on, and participate in permitting of pollution control retrofits of coal-fired power plant.
- Assist construction unions in review of air quality permitting actions before the Indiana Department of Environmental Management ("IDEM") for several natural gas-fired simple cycle peakers and combined cycle power plants.
- Assist building trades in review of air quality permitting actions for 1000-MW coal-fired power plant before the Kentucky Department for Environmental Protection. Retained as expert on BACT, emissions, permit enforceability, and public health issues in appeal of final PSD permit by Sierra Club in *Sierra Club et al. v. Natural Resources & Environmental Protection Cabinet, Division of Air Quality and Thorough Generating Company et al.* Case in progress.
- Assist coalition of towns and environmental groups in challenging air permits issued to 523 MW dual fuel (natural gas and distillate) combined-cycle power plant in Connecticut. Prepared technical comments on draft permits and 60 pages of written testimony addressing emission estimates, startup/shutdown issues, BACT/LAER analyses, and toxic air emissions. Presented testimony in adjudicatory administrative hearings before the Connecticut Department of Environmental Protection in June 2001 and December 2001.
- Assist various coalitions of unions, citizens groups, cities, public agencies, and developers in licensing and permitting of over 20 large combined cycle, simple cycle, and peaker power plants in California, Arizona, Oklahoma, Oregon, and elsewhere. Prepare analyses of and comments on applications for certification, preliminary and final staff assessments, and permits issued by local agencies. Present written and oral testimony before California Energy Commission and Arizona Power Plant and Transmission Line Siting Committee on hazards of ammonia use and transportation, health effects of air emissions, contaminated

property issues, BACT/LAER issues related to SCR and SCONOx, criteria and toxic pollutant emission estimates, MACT analyses, air quality modeling, water supply and water quality issues, and methods to reduce water use, including dry cooling, parallel dry-wet cooling, hybrid cooling, and zero liquid discharge systems.

- Assist unions, cities, and neighborhood associations in challenging an EIR issued for the proposed expansion of the Oakland Airport. Reviewed two draft EIRs and prepared a health risk assessment and extensive technical comments on air quality and public health impacts. The California Court of Appeals, First Appellate District, ruled in favor of appellants and plaintiffs, concluding that the EIR "2) erred in using outdated information in assessing the emission of toxic air contaminants (TACs) from jet aircraft; 3) failed to support its decision not to evaluate the health risks associated with the emission of TACs with meaningful analysis," thus accepting my technical arguments and requiring the Port to prepare a new EIR. See *Berkeley Keep Jets Over the Bay Committee, City of San Leandro, and City of Alameda et al. v. Board of Port Commissioners* (August 30, 2001) 111 Cal.Rptr.2d 598.
- Assisted lessor of former gas station with leaking underground storage tanks and TCE contamination from adjacent property. Lessor held option to purchase, which was forfeited based on misrepresentation by remediation contractor as to nature and extent of contamination. Remediation contractor purchased property. Reviewed regulatory agency files and advised counsel on merits of case. Case not filed.
- Advised counsel on merits of several pending actions, including a Proposition 65 case involving groundwater contamination at an explosives manufacturing firm and two former gas stations with leaking underground storage tanks.
- Assisted defendant foundry in Oakland in a lawsuit brought by neighbors alleging property contamination, nuisance, trespass, smoke, and health effects from foundry operation. Inspected and sampled plaintiff's property. Advised counsel on merits of case. Case settled.
- Assisted business owner facing eminent domain eviction. Prepared technical comments on a negative declaration for soil contamination and public health risks from air emissions from a proposed redevelopment project in San Francisco in support of a CEQA lawsuit. Case settled.
- Assisted neighborhood association representing residents living downwind of a Berkeley asphalt plant in separate nuisance and CEQA lawsuits. Prepared technical comments on air quality, odor, and noise impacts, presented testimony at commission and council meetings, participated in community workshops, and participated in settlement discussions. Cases settled. Asphalt plant was upgraded to include air emission and noise controls, including vapor collection system at truck loading station, enclosures for noisy equipment, and improved housekeeping.

- Assisted a Fortune 500 residential home builder in claims alleging health effects from faulty installation of gas appliances. Conducted indoor air quality study, advised counsel on merits of case, and participated in discussions with plaintiffs. Case settled.
- Assisted property owners in Silicon Valley in lawsuit to recover remediation costs from insurer for large TCE plume originating from a manufacturing facility. Conducted investigations to demonstrate sudden and accidental release of TCE, including groundwater modeling, development of method to date spill, preparation of chemical inventory, investigation of historical waste disposal practices and standards, and on-site sewer and storm drainage inspections and sampling. Prepared declaration in opposition to motion for summary judgment. Case settled.
- Assisted residents in east Oakland downwind of a former battery plant in class action lawsuit alleging property contamination from lead emissions. Conducted historical research and dry deposition modeling that substantiated claim. Participated in mediation at JAMS. Case settled.
- Assisted property owners in West Oakland who purchased a former gas station that had leaking underground storage tanks and groundwater contamination. Reviewed agency files and advised counsel on merits of case. Prepared declaration in opposition to summary judgment. Prepared cost estimate to remediate site. Participated in settlement discussions. Case settled.
- Consultant to counsel representing plaintiffs in two Clean Water Act lawsuits involving selenium discharges into San Francisco Bay from refineries. Reviewed files and advised counsel on merits of case. Prepared interrogatory and discovery questions, assisted in deposing opposing experts, and reviewed and interpreted treatability and other technical studies. Judge ruled in favor of plaintiffs.
- Assisted an oil company in a complaint filed by a resident of a small beach community alleging that discharges of tank farm rinse water into the sanitary sewer system caused hydrogen sulfide gas to infiltrate residence, sending occupants to hospital. Inspected accident site, interviewed parties to the event, and reviewed extensive agency files related to incident. Used chemical analysis, field simulations, mass balance calculations, sewer hydraulic simulations with SWMM44, atmospheric dispersion modeling with SCREEN3, odor analyses, and risk assessment calculations to demonstrate that the incident was caused by a faulty drain trap and inadequate slope of sewer lateral on resident's property. Prepared a detailed technical report summarizing these studies. Case settled.
- Assisted large West Coast city in suit alleging that leaking underground storage tanks on city property had damaged the waterproofing on downgradient building, causing leaks in an underground parking structure. Reviewed subsurface hydrogeologic investigations and evaluated studies conducted by others documenting leakage from underground diesel and

gasoline tanks. Inspected, tested, and evaluated waterproofing on subsurface parking structure. Waterproofing was substandard. Case settled.

- Assisted residents downwind of gravel mine and asphalt plant in Siskiyou County, California, in suit to obtain CEQA review of air permitting action. Prepared two declarations analyzing air quality and public health impacts. Judge ruled in favor of plaintiffs, closing mine and asphalt plant.
- Assisted defendant oil company on the California Central Coast in class action lawsuit alleging property damage and health effects from subsurface petroleum contamination. Reviewed documents, prepared risk calculations, and advised counsel on merits of case. Participated in settlement discussions. Case settled.
- Assisted defendant oil company in class action lawsuit alleging health impacts from remediation of petroleum contaminated site on California Central Coast. Reviewed documents, designed and conducted monitoring program, and participated in settlement discussions. Case settled.
- Consultant to attorneys evaluating a potential challenge of USFWS actions under CVPIA section 3406(b)(2). Reviewed agency files and collected and analyzed hydrology, water quality, and fishery data. Advised counsel on merits of case. Case not filed.
- Assisted residents downwind of a Carson refinery in class action lawsuit involving soil and groundwater contamination, nuisance, property damage, and health effects from air emissions. Reviewed files and provided advise on contaminated soil and groundwater, toxic emissions, and health risks. Prepared declaration on refinery fugitive emissions. Prepared deposition questions and reviewed deposition transcripts on air quality, soil contamination, odors, and health impacts. Case settled.
- Assisted residents downwind of a Contra Costa refinery who were affected by an accidental release of naphtha. Characterized spilled naphtha, estimated emissions, and modeled ambient concentrations of hydrocarbons and sulfur compounds. Deposed. Presented testimony in binding arbitration at JAMS. Judge found in favor of plaintiffs.
- Assisted residents downwind of Contra Costa County refinery in class action lawsuit alleging property damage, nuisance, and health effects from several large accidents as well as routine operations. Reviewed files and prepared analyses of environmental impacts. Prepared declarations, deposed, and presented testimony before jury in one trial and judge in second. Case pending.
- Assisted business owner claiming damages from dust, noise, and vibration during a sewer construction project in San Francisco. Reviewed agency files and PM10 monitoring data and advised counsel on merits of case. Case settled.
- Assisted residents downwind of Contra Costa County refinery in class action lawsuit alleging property damage, nuisance, and health effects. Prepared declaration in opposition to

summary judgment, deposed, and presented expert testimony on accidental releases, odor, and nuisance before jury. Case thrown out by judge, but reversed on appeal and to be retried.

- Presented testimony in small claims court on behalf of residents claiming health effects from hydrogen sulfide from flaring emissions triggered by a power outage at a Contra Costa County refinery. Analyzed meteorological and air quality data and evaluated potential health risks of exposure to low concentrations of hydrogen sulfide. Judge awarded damages to plaintiffs.
- Assisted construction unions in challenging PSD permit for an Indiana steel mill. Prepared technical comments on draft PSD permit, drafted 70-page appeal of agency permit action to the Environmental Appeals Board challenging permit based on faulty BACT analysis for electric arc furnace and reheat furnace and faulty permit conditions, among others, and drafted briefs responding to four parties. EPA Region V and the EPA General Counsel intervened as amici, supporting petitioners. EAB ruled in favor of petitioners, remanding permit to IDEM on three key issues, including BACT for the reheat furnace and lead emissions from the EAF. Drafted motion to reconsider three issues. Prepared 69 pages of technical comments on revised draft PSD permit. Drafted second EAB appeal addressing lead emissions from the EAF and BACT for reheat furnace based on European experience with SCR/SNCR. Case settled. Permit was substantially improved. See *In re: Steel Dynamics, Inc.*, PSD Appeal Nos. 99-4 & 99-5 (EAB June 22, 2000).
- Assisted defendant urea manufacturer in Alaska in negotiations with USEPA to seek relief from penalties for alleged violations of the Clean Air Act. Reviewed and evaluated regulatory files and monitoring data, prepared technical analysis demonstrating that permit limits were not violated, and participated in negotiations with EPA to dismiss action. Fines were substantially reduced and case closed.
- Assisted construction unions in challenging PSD permitting action for an Indiana grain mill. Prepared technical comments on draft PSD permit and assisted counsel draft appeal of agency permit action to the Environmental Appeals Board challenging permit based on faulty BACT analyses for heaters and boilers and faulty permit conditions, among others. Case settled.
- As part of a consent decree settling a CEQA lawsuit, assisted neighbors of a large west coast port in negotiations with port authority to secure mitigation for air quality impacts. Prepared technical comments on mobile source air quality impacts and mitigation and negotiated a \$9 million CEQA mitigation package. Currently representing neighbors on technical advisory committee established by port to implement the air quality mitigation program.
- Assisted construction unions in challenging permitting action for a California hazardous waste incinerator. Prepared technical comments on draft permit, assisted counsel prepare appeal of EPA permit to the Environmental Appeals Board. Participated in settlement discussions on technical issues with applicant and EPA Region 9. Case settled.

- Assisted environmental group in challenging DTSC Negative Declaration on a hazardous waste treatment facility. Prepared technical comments on risk of upset, water, and health risks. Writ of mandamus issued.
- Assisted several neighborhood associations and cities impacted by quarries, asphalt plants, and cement plants in Alameda, Shasta, Sonoma, and Mendocino counties in obtaining mitigations for dust, air quality, public health, traffic, and noise impacts from facility operations and proposed expansions.
- For over 100 industrial facilities, commercial/campus, and redevelopment projects, developed the record in preparation for CEQA and NEPA lawsuits. Prepared technical comments on hazardous materials, solid wastes, public utilities, noise, worker safety, air quality, public health, water resources, water quality, traffic, and risk of upset sections of EIRs, EISs, initial studies, and negative declarations. Assisted counsel in drafting petitions and briefs and prepared declarations.
- For several large commercial development projects and airports, assisted applicant and counsel prepare defensible CEQA documents, respond to comments, and identify and evaluate "all feasible" mitigation to avoid CEQA challenges. This work included developing mitigation programs to reduce traffic-related air quality impacts based on energy conservation programs, solar, low-emission vehicles, alternative fuels, exhaust treatments, and transportation management associations.

SITE INVESTIGATION/REMEDATION/CLOSURE

- Technical manager and principal engineer for characterization, remediation, and closure of waste management units at former Colorado oil shale plant. Constituents of concern included BTEX, As, 1,1,1-TCA, and TPH. Completed groundwater monitoring programs, site assessments, work plans, and closure plans for seven process water holding ponds, a refinery sewer system, and processed shale disposal area. Managed design and construction of groundwater treatment system and removal actions and obtained clean closure.
- Principal engineer for characterization, remediation, and closure of process water ponds at a former lanthanide processing plant in Colorado. Designed and implemented groundwater monitoring program and site assessments and prepared closure plan.
- Advised the city of Sacramento on redevelopment of two former railyards. Reviewed work plans, site investigations, risk assessment, RAPS, RI/FSs, and CEQA documents. Participated in the development of mitigation strategies to protect construction and utility workers and the public during remediation, redevelopment, and use of the site, including buffer zones, subslab venting, rail berm containment structure, and an environmental oversight plan.

- Provided technical support for the investigation of a former sanitary landfill that was redeveloped as single family homes. Reviewed and/or prepared portions of numerous documents, including health risk assessments, preliminary endangerment assessments, site investigation reports, work plans, and RI/FSs. Historical research to identify historic waste disposal practices to prepare a preliminary endangerment assessment. Acquired, reviewed, and analyzed the files of 18 federal, state, and local agencies, three sets of construction field notes, analyzed 21 aerial photographs and interviewed 14 individuals associated with operation of former landfill. Assisted counsel in defending lawsuit brought by residents alleging health impacts and diminution of property value due to residual contamination. Prepared summary reports.
- Technical oversight of characterization and remediation of a nitrate plume at an explosives manufacturing facility in Lincoln, CA. Provided interface between owners and consultants. Reviewed site assessments, work plans, closure plans, and RI/FSs.
- Consultant to owner of large western molybdenum mine proposed for NPL listing. Participated in negotiations to scope out consent order and develop scope of work. Participated in studies to determine premining groundwater background to evaluate applicability of water quality standards. Served on technical committees to develop alternatives to mitigate impacts and close the facility, including resloping and grading, various thickness and types of covers, and reclamation. This work included developing and evaluating methods to control surface runoff and erosion, mitigate impacts of acid rock drainage on surface and ground waters, and stabilize nine waste rock piles containing 328 million tons of pyrite-rich, mixed volcanic waste rock (andesites, rhyolite, tuff). Evaluated stability of waste rock piles. Represented client in hearings and meetings with state and federal oversight agencies.

REGULATORY PERMITTING/NEGOTIATIONS

- Prepared Authority to Construct Permit for remediation of a large petroleum-contaminated site on the Central Coast. Negotiated conditions with agencies and secured permits.
- Prepared Authority to Construct Permit for remediation of a former oil field on the Central Coast. Participated in negotiations with agencies and secured permits.
- Prepared and/or reviewed hundreds of environmental permits, including NPDES, UIC, Stormwater, Authority to Construct, Prevention of Significant Deterioration, New Source Review, and RCRA, among others.
- Participated in the development of the CARB document, *Guidance for Power Plant Siting and Best Available Control Technology*, including attending public workshops and filing technical comments.

- Performed data analyses in support of adoption of emergency power restoration standards by the Public Utilities Commission for “major” power outages, where major is an outage that simultaneously affects 10% of the customer base.
- Drafted portions of the Good Neighbor Ordinance to grant Contra Costa County greater authority over safety of local industry, particularly chemical plants and refineries.
- Participated in drafting BAAQMD Regulation 8, Rule 28, Pressure Relief Devices, including participation in public workshops, review of staff reports, draft rules and other technical materials, preparation of technical comments on staff proposals, research on availability and costs of methods to control PRV releases, and negotiations with staff.
- Participated in amending BAAQMD Regulation 8, Rule 18, Valves and Connectors, including participation in public workshops, review of staff reports, proposed rules and other supporting technical material, preparation of technical comments on staff proposals, research on availability and cost of low-leak technology, and negotiations with staff.
- Participated in amending BAAQMD Regulation 8, Rule 25, Pumps and Compressors, including participation in public workshops, review of staff reports, proposed rules, and other supporting technical material, preparation of technical comments on staff proposals, research on availability and costs of low-leak and seal-less technology, and negotiations with staff.
- Participated in amending BAAQMD Regulation 8, Rule 5, Storage of Organic Liquids, including participation in public workshops, review of staff reports, proposed rules, and other supporting technical material, preparation of technical comments on staff proposals, research on availability and costs of controlling tank emissions, and presentation of testimony before the Board.
- Participated in amending BAAQMD Regulation 8, Rule 18, Valves and Connectors at Petroleum Refinery Complexes, including participation in public workshops, review of staff reports, proposed rules and other supporting technical material, preparation of technical comments on staff proposals, research on availability and costs of low-leak technology, and presentation of testimony before the Board.
- Participated in amending BAAQMD Regulation 8, Rule 22, Valves and Flanges at Chemical Plants, etc, including participation in public workshops, review of staff reports, proposed rules, and other supporting technical material, preparation of technical comments on staff proposals, research on availability and costs of low-leak technology, and presentation of testimony before the Board.
- Participated in amending BAAQMD Regulation 8, Rule 25, Pump and Compressor Seals, including participation in public workshops, review of staff reports, proposed rules, and other supporting technical material, preparation of technical comments on staff proposals, research on availability of low-leak technology, and presentation of testimony before the Board.

- Participated in the development of the BAAQMD Regulation 2, Rule 5, Toxics, including participation in public workshops, review of staff proposals, and preparation of technical comments.
- Participated in the development of SCAQMD Rule 1402, Control of Toxic Air Contaminants from Existing Sources, and proposed amendments to Rule 1401, New Source Review of Toxic Air Contaminants, in 1993, including review of staff proposals and preparation of technical comments on same.
- Participated in the development of the Sunnyvale Ordinance to Regulate the Storage, Use and Handling of Toxic Gas, which was designed to provide engineering controls for gases that are not otherwise regulated by the Uniform Fire Code.
- Participated in the drafting of the Statewide Water Quality Control Plans for Inland Surface Waters and Enclosed Bays and Estuaries, including participation in workshops, review of draft plans, preparation of technical comments on draft plans, and presentation of testimony before the SWRCB.
- Participated in developing Se permit effluent limitations for the five Bay Area refineries, including review of staff proposals, statistical analyses of Se effluent data, review of literature on aquatic toxicity of Se, preparation of technical comments on several staff proposals, and presentation of testimony before the Bay Area RWQCB.
- Represented the California Department of Water Resources in the 1991 Bay-Delta Hearings before the State Water Resources Control Board, presenting sworn expert testimony with cross examination and rebuttal on a striped bass model developed by the California Department of Fish and Game.
- Represented the State Water Contractors in the 1987 Bay-Delta Hearings before the State Water Resources Control Board, presenting sworn expert testimony with cross examination and rebuttal on natural flows, historical salinity trends in San Francisco Bay, Delta outflow, and hydrodynamics of the South Bay.
- Represented interveners in the licensing of over 20 natural-gas-fired power plants and one coal gasification plant at the California Energy Commission and elsewhere. Reviewed and prepared technical comments on applications for certification, preliminary staff assessments, final staff assessments, preliminary determinations of compliance, final determinations of compliance, and prevention of significant deterioration permits in the areas of air quality, water supply, water quality, biology, public health, worker safety, transportation, site contamination, cooling systems, and hazardous materials. Presented written and oral testimony in evidentiary hearings with cross examination and rebuttal. Participated in technical workshops.
- Represented several parties in the proposed merger of San Diego Gas & Electric and Southern California Edison. Prepared independent technical analyses on health risks, air

quality, and water quality. Presented written and oral testimony before the Public Utilities Commission administrative law judge with cross examination and rebuttal.

- Represented a PRP in negotiations with local health and other agencies to establish impact of subsurface contamination on overlying residential properties. Reviewed health studies prepared by agency consultants and worked with agencies and their consultants to evaluate health risks.

WATER QUALITY/RESOURCES

- Directed and participated in research on environmental impacts of energy development in the Colorado River Basin, including contamination of surface and subsurface waters and modeling of flow and chemical transport through fractured aquifers.
- Played a major role in Northern California water resource planning studies since the early 1970s. Prepared portions of the Basin Plans for the Sacramento, San Joaquin, and Delta basins including sections on water supply, water quality, beneficial uses, waste load allocation, and agricultural drainage. Developed water quality models for the Sacramento and San Joaquin Rivers.
- Conducted hundreds of studies over the past 30 years on Delta water supplies and the impacts of exports from the Delta on water quality and biological resources of the Central Valley, Sacramento-San Joaquin Delta, and San Francisco Bay. Typical examples include:
 1. Evaluate historical trends in salinity, temperature, and flow in San Francisco Bay and upstream rivers to determine impacts of water exports on the estuary;
 2. Evaluate the role of exports and natural factors on the food web by exploring the relationship between salinity and primary productivity in San Francisco Bay, upstream rivers, and ocean;
 3. Evaluate the effects of exports, other in-Delta, and upstream factors on the abundance of salmon and striped bass;
 4. Review and critique agency fishery models that link water exports with the abundance of striped bass and salmon;
 5. Develop a model based on GLMs to estimate the relative impact of exports, water facility operating variables, tidal phase, salinity, temperature, and other variables on the survival of salmon smolts as they migrate through the Delta;
 6. Reconstruct the natural hydrology of the Central Valley using water balances, vegetation mapping, reservoir operation models to simulate flood basins, precipitation records, tree ring research, and historical research;
 7. Evaluate the relationship between biological indicators of estuary health and down-estuary position of a salinity surrogate (X2);

8. Use real-time fisheries monitoring data to quantify impact of exports on fish migration;
 9. Refine/develop statistical theory of autocorrelation and use to assess strength of relationships between biological and flow variables;
 10. Collect, compile, and analyze water quality and toxicity data for surface waters in the Central Valley to assess the role of water quality in fishery declines;
 11. Assess mitigation measures, including habitat restoration and changes in water project operation, to minimize fishery impacts;
 12. Evaluate the impact of unscreened agricultural water diversions on abundance of larval fish;
 13. Prepare and present testimony on the impacts of water resources development on Bay hydrodynamics, salinity, and temperature in water rights hearings;
 14. Evaluate the impact of boat wakes on shallow water habitat, including interpretation of historical aerial photographs;
 15. Evaluate the hydrodynamic and water quality impacts of converting Delta islands into reservoirs;
 16. Use a hydrodynamic model to simulate the distribution of larval fish in a tidally influenced estuary;
 17. Identify and evaluate non-export factors that may have contributed to fishery declines, including predation, shifts in oceanic conditions, aquatic toxicity from pesticides and mining wastes, salinity intrusion from channel dredging, loss of riparian and marsh habitat, sedimentation from upstream land alternations, and changes in dissolved oxygen, flow, and temperature below dams.
- Developed, directed, and participated in a broad-based research program on environmental issues and control technology for energy industries including petroleum, oil shale, coal mining, and coal slurry transport. Research included evaluation of air and water pollution, development of novel, low-cost technology to treat and dispose of wastes, and development and application of geohydrologic models to evaluate subsurface contamination from in-situ retorting. The program consisted of government and industry contracts and employed 45 technical and administrative personnel.
 - Coordinated an industry task force established to investigate the occurrence, causes, and solutions for corrosion/erosion and mechanical/engineering failures in the waterside systems (e.g., condensers, steam generation equipment) of power plants. Corrosion/erosion failures caused by water and steam contamination that were investigated included waterside

corrosion caused by poor microbiological treatment of cooling water, steam-side corrosion caused by ammonia-oxygen attack of copper alloys, stress-corrosion cracking of copper alloys in the air cooling sections of condensers, tube sheet leaks, oxygen in-leakage through condensers, volatilization of silica in boilers and carry over and deposition on turbine blades, and iron corrosion on boiler tube walls. Mechanical/engineering failures investigated included: steam impingement attack on the steam side of condenser tubes, tube-to-tube-sheet joint leakage, flow-induced vibration, structural design problems, and mechanical failures due to stresses induced by shutdown, startup and cycling duty, among others. Worked with electric utility plant owners/operators, condenser and boiler vendors, and architect/engineers to collect data to document the occurrence of and causes for these problems, prepared reports summarizing the investigations, and presented the results and participated on a committee of industry experts tasked with identifying solutions to prevent condenser failures.

- Evaluated the cost effectiveness and technical feasibility of using dry cooling and parallel dry-wet cooling to reduce water demands of several large natural-gas fired power plants in California and Arizona.
- Designed and prepared cost estimates for several dry cooling systems (e.g., fin fan heat exchangers) used in chemical plants and refineries.
- Designed, evaluated, and costed several zero liquid discharge systems for power plants.
- Evaluated the impact of agricultural and mining practices on surface water quality of Central Valley streams. Represented municipal water agencies on several federal and state advisory committees tasked with gathering and assessing relevant technical information, developing work plans, and providing oversight of technical work to investigate toxicity issues in the watershed.

AIR QUALITY/PUBLIC HEALTH

- Prepared or reviewed the air quality and public health sections of hundreds of EIRs and EISs on a wide range of industrial, commercial and residential projects.
- Prepared or reviewed hundreds of NSR and PSD permits for a wide range of industrial facilities.
- Designed, implemented, and directed a 2-year-long community air quality monitoring program to assure that residents downwind of a petroleum-contaminated site were not impacted during remediation of petroleum-contaminated soils. The program included real-time monitoring of particulates, diesel exhaust, and BTEX and time integrated monitoring for over 100 chemicals.
- Designed, implemented, and directed a 5-year long source, industrial hygiene, and ambient monitoring program to characterize air emissions, employee exposure, and downwind environmental impacts of a first-generation shale oil plant. The program included stack monitoring of heaters, boilers, incinerators, sulfur recovery units, rock crushers, API

separator vents, and wastewater pond fugitives for arsenic, cadmium, chlorine, chromium, mercury, 15 organic indicators (e.g., quinoline, pyrrole, benzo(a)pyrene, thiophene, benzene), sulfur gases, hydrogen cyanide, and ammonia. In many cases, new methods had to be developed or existing methods modified to accommodate the complex matrices of shale plant gases.

- Conducted investigations on the impact of diesel exhaust from truck traffic from a wide range of facilities including mines, large retail centers, light industrial uses, and sports facilities. Conducted traffic surveys, continuously monitored diesel exhaust using an aethalometer, and prepared health risk assessments using resulting data.
- Conducted indoor air quality investigations to assess exposure to natural gas leaks, pesticides, molds and fungi, soil gas from subsurface contamination, and outgassing of carpets, drapes, furniture and construction materials. Prepared health risk assessments using collected data.
- Prepared health risk assessments, emission inventories, air quality analyses, and assisted in the permitting of over 70 1 to 2 MW emergency diesel generators.
- Prepare over 100 health risk assessments, endangerment assessments, and other health-based studies for a wide range of industrial facilities.
- Developed methods to monitor trace elements in gas streams, including a continuous real-time monitor based on the Zeeman atomic absorption spectrometer, to continuously measure mercury and other elements.
- Performed nuisance investigations (odor, noise, dust, smoke, indoor air quality, soil contamination) for businesses, industrial facilities, and residences located proximate to and downwind of pollution sources.

Dr. Pless has over 10 years of experience in environmental engineering and science conducting and managing interdisciplinary environmental research projects and preparing and reviewing environmental permits and other documents for U.S. and European stakeholder groups. This broad-based experience includes air quality and pollution control; water quality, water supply, and water pollution control; noise studies; CEQA review; industrial ecology and risk assessment; and development and use of a wide range of environmental software.

EDUCATION

Doctorate in Environmental Science and Engineering, University of California, Los Angeles, 2001

M.S. Biology (Botany/Ecology), Technical University of Munich, Germany, 1991

PROFESSIONAL HISTORY

Leson Environmental Consulting, Berkeley, CA, Environmental Scientist, 1997-Present

University of California Los Angeles, Graduate Research Assistant/Teaching Assistant, 1994-96

ECON Research and Development, Environmental Scientist, Ingelheim, Germany, 1992-93

Biocontrol, Environmental Projects Manager, Ingelheim, Germany, 1991-92

REPRESENTATIVE EXPERIENCE

Air Quality and Pollution Control

Experience in all aspects of air quality and pollution control including attainment and non-attainment new source review, PSD and Title V permitting; BACT, LAER, RACT, BARCT, and MACT analyses; technology evaluations and cost-effectiveness analyses; criteria and toxic pollutant emission inventories; emission offsets; ambient and source monitoring. Some typical projects include:

- For an Indiana steel mill, evaluated technology to control NO_x and CO emissions from fired sources, including electric arc furnaces and reheat furnaces, to establish BACT. This required a comprehensive review of U.S. and European operating experience. The lowest emission levels were being achieved by steel mills using SCR and SNCR in Sweden and The Netherlands.

- For a California petroleum coke calciner, evaluated technology to control NO_x, CO, VOCs, and PM₁₀ emissions from the kiln and pyroscrubbers to establish BACT and LAER. This required a review of state and federal clearinghouses, working with regulatory agencies and pollution control vendors, and obtaining and reviewing permits and emissions data from other similar facilities. The best-controlled facilities were located in the SCAQMD.
- For a Kentucky coal-fired power plant, identified the lowest NO_x levels that had been permitted and demonstrated in practice to establish BACT. Reviewed operating experience of European, Japanese, and U.S. facilities and evaluated continuous emission monitoring data. The lowest NO_x levels had been permitted and achieved in Denmark and in the U.S. in Texas and New York.
- In support of efforts to lower the CO BACT level for power plant emissions, evaluated the contribution of CO emissions to tropospheric ozone formation and coauthored report on same.
- Critically reviewed and prepared technical comments on draft PSD permits for several natural-gas fired power plants in California, Indiana, and Oregon. The comments addressed emission inventories, BACT, case-by-case MACT, compliance monitoring, cost-effectiveness analyses, and enforceability of permit limits.
- For a California refinery, evaluated technology to control NO_x and CO emissions from CO Boilers to establish RACT/BARCT to comply with BAAQMD Rule 9-10. This required a review of BACT/RACT/LAER clearinghouses, working with regulatory agencies across the U.S., and reviewing federal and state regulations and State Implementation Plans. The lowest levels were required in a SCAQMD rule and in the Texas SIP.
- In conjunction with the permitting of several residential and commercial developments, conducted studies to determine baseline concentrations of diesel exhaust using an aethalometer.
- For several California refineries, evaluated compliance of fired sources with BAAQMD Rule 9-10. This required evaluation and review of hundreds of source tests to determine if refinery-wide emission caps and compliance monitoring provisions were being met.
- Critically reviewed and prepared technical comments on draft Title V permits for several refineries and other industrial facilities in California.
- Critically reviewed and prepared technical comments on the air quality, biology, noise, and public health sections of CEQA documents (EIRs, Initial Studies, Mitigated Negative Declarations) for several commercial, residential, and industrial projects in California.
- In support of several federal lawsuits filed under the Clean Air Act, prepared cost-effectiveness analyses for SCR and oxidation catalysts for simple cycle gas turbines and evaluated opacity data.
- Provided comprehensive environmental and regulatory services for an industrial laundry chain. Facilitated permit process with the South Coast Air Quality Management District. Developed test protocol for VOC emissions, conducted field tests, and used mass balance methods to estimate emissions. Reduced disposal costs for solvent-

containing waste streams by identifying alternative disposal options. Performed health risk screening for air toxics emissions. Provided permitting support with SCAQMD. Renegotiated sewer surcharges with wastewater treatment plant. Identified new customers for shop-towel recycling services.

- Designed computer model to predict performance of biological air pollution control as part of a collaborative technology assessment project, co-funded by several major chemical manufacturers.
- Experience using a wide range of environmental software, including air dispersion models, air emission software, and developing applications using database programs and GIS.

Water Quality and Pollution Control

Experience in all phases of water quality and pollution control, including surface water and ground water quality and supply studies, evaluating water and wastewater treatment technologies, and identifying, evaluating and implementing pollution controls. Some typical projects include:

- For a homeowner's association, reviewed a CA Coastal Commission staff report on the replacement of 12,000 linear feet of wooden bulkhead with PVC sheet pile armor. Researched and evaluated impact of proposed project on lagoon water quality, including sediment resuspension, leaching of additives and sealants, and long-term stability. Summarized results in letter report. This work is ongoing.
- Evaluated impact of on-shore oil drilling activities on large-scale coastal erosion in Nigeria. This work is ongoing.
- For a 500-MW combined-cycle power plant, prepared a study to evaluate the impact of proposed groundwater pumping on local water quality and supply, including a nearby stream, springs, and a spring-fed waterfall. The study was docketed with the California Energy Commission and summarized in a journal article.
- For a 500-MW combined-cycle power plant, identified and evaluated methods to reduce water use and water quality impacts. These included the use of zero liquid discharge systems and alternative cooling technologies, including dry and parallel wet-dry cooling. Prepared cost analyses and evaluated impact of options on water resources. This work led to a settlement in which parallel wet dry cooling and a crystallizer were selected, replacing 100% groundwater pumping and wastewater disposal to evaporation ponds.

Applied Ecology, Industrial Ecology and Risk Assessment

Experience in applied ecology, industrial ecology and risk assessment, including human and ecological risk assessments, life cycle assessment, evaluation and licensing of new chemicals, and fate and transport studies of contaminants. Experienced in botanical, phytoplankton, and intertidal species systematics and water chemistry analyses. Some typical projects include:

- Evaluated likelihood that measured organochlorine pesticide concentrations at a U.S. naval air station are residuals from past applications of these pesticides consistent with manufacturers' recommendations.
- For a 180-MW geothermal power plant, evaluated the impacts of plant construction and operation on the fragile desert ecosystem in the Salton Sea area. This work included baseline noise monitoring and assessing the impact of noise, brine handling and disposal, and air emissions on local biota, public health, and welfare.
- Evaluated the public health impacts of locating big box retail developments in densely populated areas in California and Hawaii. The impacts of diesel exhaust emissions and noise on surrounding residential communities were measured and evaluated. This work is continuing.
- Designed and managed toxicological study on potential interference of delta-9-tetrahydrocannabinol in food products with U.S. employee drug testing. Coauthored peer-reviewed publication.
- Conducted technical, ecological, and economic assessments of product lines from agricultural fiber crops for European equipment manufacturer. Coauthored proprietary client reports.
- Prepared human health risk assessments of air emissions from several industrial and commercial establishments, including power plants, refineries, and commercial laundries.
- Managed and conducted studies to license new pesticides. This work included the evaluation of the adequacy and identification of deficiencies in existing physicochemical and health effects data sets, initiating and supervising studies to fill the data gaps, conducting fate and transport studies, and QA/QC compliance at subcontractor laboratories. Prepared licensing applications and coordinated their progress with German registration agencies. This work led to regulatory approval of several pesticide applications in less than 6 months.
- Designed and implemented database on physico-chemical properties and environmental and health impacts of pesticides.
- Developed life cycle assessment methodology for industrial products, including agricultural fiber crops and mineral fibers. Analyzed technical feasibility and markets for thermal insulation materials from plant fibers and conducted comparative life cycle assessments.
- Designed research protocols for a coastal ecological inventory. Developed sampling methodologies, coordinated field sampling, identified species in intertidal zone, and analyzed data.
- Designed and conducted limnological study on effects of physico-chemical parameters on phytoplankton succession; performed water chemistry analyses and identified phytoplankton species. Co-authored two journal articles on results.
- Conducted and organized underwater surveying and mapping of macrophytes in many lakes and rivers in Sweden and Germany as ecological indicators for the health of limnological ecosystems.

- Provided pro-bono consulting for the Pine Ridge Reservation in South Dakota. Assessed environmental improvement and economic development projects and recommended methods to improve the quality of life.

COMMENTS

Los Angeles World Airports ("LAWA" or "the Applicant"), the operator of the Los Angeles International Airport ("LAX"), has published a Draft Master Plan Addendum, a Supplement to the Draft Environmental Impact Statement/Environmental Impact Report¹ ("Supplement"), and Airport Layout Plans Package on the modernization of LAX ("Project"). These documents supplement the Draft Environmental Impact Statement/Environmental Impact Report² ("Draft EIS/EIR") and add discussion of Alternative D to the previously discussed Master Plan alternatives.

We previously submitted comments on the Draft EIS/EIR that demonstrated the failure of the Draft EIS/EIR to meet the requirements of CEQA and NEPA. (Comments on Hydrology and Water Quality, LAX Master Plan Draft EIS/EIR (July 13, 2001) by J. Phyllis Fox, Ph.D., Attachment D to September 18, 2001 Comments Submitted on Behalf of the City of El Segundo by Shute, Mihaly & Weinberger ("2001 Fox Comments").)

The Draft EIS/EIR failed to analyze all impacts from the Project and the mitigation measure proposed to mitigate significant hydrology and water quality impacts from Project Alternatives A through C was inadequate. Further shortcomings consisted of a substantial underestimate of pollutant loads due to the use of a flawed methodology, the omission of pollutants, and the use of incorrect datasets and runoff coefficients.

With few exceptions, the Supplement ignored our comments and proceeded to use the same methodology and datasets for its revised runoff estimates and presents a virtually unchanged mitigation measure. Thus, the Supplement is inadequate and does not meet the requirements of CEQA and NEPA. The many areas in which the Draft EIR/EIS and the Supplement are deficient must be addressed, the impacts on hydrology and water quality reassessed, an acceptable mitigation measure(s) must be developed, and the documents must be recirculated for public review.

¹ LAX Master Plan, Supplement to the Draft Environmental Impact Statement/Environmental Impact Report, July 2003.

² LAX Master Plan, Draft Environmental Impact Statement/Environmental Impact Report, January 2001.

The following sections provide our comments on the changes made in the Supplement and offers additional commentary on the Project's hydrology and water quality impacts.

I. STORMWATER POLLUTANT LOAD ESTIMATES ARE FLAWED

In our previous comments on the Draft EIS/EIR, we demonstrated that the Project analysis substantially underestimated pollutant loads in stormwater runoff because a flawed methodology and incorrect data sets were used. (2001 Fox Comments, pp. 5-19.) With few exceptions, the Supplement ignored these comments and proceeded to use the same methodology and datasets described in the Draft EIS/EIR Technical Report 6, Hydrology and Water Quality ("TR6"). Consequently, the revised estimates for stormwater pollutant loads presented in the Supplement are also underestimated. Our previous comments on the methodology and data used to analyze stormwater runoff for the various Project alternatives remain applicable and the calculations should be revised accordingly. The following discussion relates to the few changes in the Supplement's methodology or data and provides additional comments regarding the environmental baseline against which Project impacts are evaluated.

I.A Pollutants Of Concern Not Properly Selected

In addition to the nine pollutants analyzed in the Draft EIS/EIR, pollutants – total suspended solids ("TSS"), total phosphorus ("TP"), total Kjeldahl nitrogen ("TKN"), 5-day biochemical oxygen demand ("BOD₅"), chemical oxygen demand ("COD"), oil and grease ("O&G"), and total copper, total lead, total zinc – the Supplement has expanded its list by four additional pollutants, *i.e.* ammonia, total coliform, fecal coliform, and fecal *Enterococcus* bacteria, for the estimation of average annual pollutant loads for all alternatives. However, as we previously pointed out in our comments on the Draft EIS/EIR, several other pollutants should have also been included in the analysis including cadmium, chromium, nickel, mercury, and silver as well as polycyclic aromatic hydrocarbons ("PAH"). (2001 Fox Comments, II.D, pp. 9/10.) The Supplement entirely ignored this recommendation and does not provide any additional information on why it chose to exclude these pollutants from its analysis.

I.B Toxicity Was Not Considered

As discussed in our previous comments, the Draft EIS/EIR should have evaluated the fact that stormwater runoff from the vicinity of the project is known to be toxic to marine organisms. Pollutants of concern include pathogens and viruses, dioxins, furans, and other chlorinated organics, polycyclic aromatic hydrocarbons, metals, and pesticides. (2001 Fox Comments, II.E, p. 10-18.) The

only mitigation proposed to reduce water quality impacts requires "no net increase in loads of pollutants of concern." (Draft EIS/EIR, p. 4-547.) However, if the pollutants responsible for the observed toxicity are not included in the analysis and hence not subject to control, this mitigation measure would do nothing to mitigate toxicity from increases in stormwater runoff caused by the Project. The Supplement continues to ignore this issue.

LC Event Mean Concentrations Underestimated

The analysis of the Project's water quality impacts is based on an estimate of pollutant loads discharged into Santa Monica Bay caused by changes in stormwater runoff volume as a result of changes in land use due to the Project. Both the Draft EIS/EIR and the Supplement estimated pollutant loads by multiplying the event mean concentrations ("EMCs") for stormwater runoff by the annual volume of stormwater runoff. (Draft EIS/EIR, TR6³, pp. 20-25; Supplement, TRS-5⁴, p. 2.)

The Draft EIS/EIR used 1994-1999 stormwater monitoring data reported by the Los Angeles County Department of Public Works ("LACDPW") for all land uses (industrial, commercial, residential, open space, transportation) except airport operations and airport open space. For land uses categorized as airport operations and airport open spaces, the DEIR relied on a joint study by the American Association of Airport Executives ("AAAE") and the Airport Research and Development Foundation ("ARDF"), the "Ostrom Study"⁵, which monitored the quality of stormwater runoff from 65 airports⁶ nationwide in preparation for the 1992 stormwater group permit. (Draft EIS/EIR, TR6, p. 21; Supplement, TRS-5, p. 2.) The Draft EIS/EIR used AA AE/ARDF data for total suspended solids ("TSS"), total phosphorus ("TP"), total Kjeldahl nitrogen ("TKN"), oil and grease ("O&G"), 5-day biochemical oxygen demand ("BOD₅"), and chemical oxygen demand ("COD"). Because the AA AE/ARDF study did not include data for total copper ("Cu"), total lead ("Pb"), and total zinc ("Zn"), the Draft EIS/EIR

³ LAX Master Plan Draft Environmental Impact Statement/Environmental Impact Report, Technical Report, 6. Hydrology and Water Quality January 2001.

⁴ LAX Master Plan Supplement to the Draft Environmental Impact Statement/Environmental Impact Report, Technical Report, S-5. Hydrology and Water Quality, July 2003.

⁵ Brenda Ostrom, Predicting Pollutant Loads in Airport Storm Water Runoff -- Advanced Spatial Statistics, May 12, 1994.

⁶ In contrast, Supplement TRS-5, p. 2, specifies that the storm water samples were collected at "over 605 airports." Neither the Draft EIS/EIR nor the Supplement provided a description of the methodology of the Ostrom study. It thus remains unclear how many airports were sampled, for how many years data were collected, how the data were analyzed, and so forth.

relied on LACDPW data developed for the transportation sector for these three pollutants. (Draft EIS/EIR, TR6, pp. 20-24.)

In our previous comments, we pointed out that a) the LACDPW EMC dataset used by the Draft EIS/EIR had been superceded and b) the use of the AAAE/ ARDF data is inappropriate for characterizing stormwater runoff pollutant loads at LAX. (2001 Fox Comments, II.A, pp. 5/6.) The AAAE/ ARDF data represent a nationwide average from airports with dissimilar levels of operational activities, located in varying climate zones with greatly differing precipitation volumes and patterns. These data are entirely unsuitable to characterize runoff from an airport as busy as LAX, located in a desert climate where precipitation during most of the year is non-existing and most runoff occurs during a few major storm events during the rainy season.

The Supplement updated the LACDPW data for the period 1999-2000 as recommended, however it continued to use the same AAAE/ ARDF data for land uses categorized as airport operations and airport open spaces for the above listed pollutants. As an explanation, the Supplement offers that "inquiries were made to AAAE and other sources to obtain the original AAAE raw data" and that "[t]he goal of these inquiries was to isolate the EMCs collected from the four airports located in what is referred to in the Ostrom Study as Rainfall Region 5, which includes portions of southwestern Colorado, southern Utah, southern Nevada, western New Mexico, Arizona, and southern California. However, the raw data could not be obtained from AAAE or from other sources to which inquiries were made. Therefore, no new airport EMCs or EMCs specific to LAX are used in this Supplement to the Draft EIS/EIR." (Supplement, TRS-5, p. 2.) Obviously, the Supplement recognized that the use of a nationwide average is inappropriate to characterize EMCs at LAX. However, it declined to provide any reasons why it still chose those inappropriate data when it did not succeed to obtain a regional data subset.

The EMCs based on local LACDPW data for the transportation sector are much higher (up to four times) for all pollutants than the AAAE/ ARDF data as shown in the inset table below. (See Supplement, TRS-5, p. 3, Table S1.)

Pollutant	Event Mean Concentration (mg/L)		(LACDPW EMC)/ (AAAE/ARDF EMC)
	LACDPW	AAAE/ARDF	
TSS	78	19.01	410%
TP	0.44	0.24	183%
TKN	1.9	1.07	178%
O&G	3.1	2.29	135%
BOD ₅	21	6.58	319%
COD	50	45.7	109%

Obviously, the use of AAAE/ARDF data instead of LACDPW data for the transportation sector leads to a substantial underestimate for pollutant loads from stormwater runoff from airport operations and airport open spaces for these pollutants. With few exceptions, the LACDPW's EMCs for most land uses are much higher than those reported by the AAAE/ARDF. (See Supplement, TRS-5 Table S-1, p. 3.)

Consequently, any change in land use to the airport operations/airport open space land use will result in a decrease of total pollutant loads in comparison with the baseline for most of the above mentioned pollutants. Not surprisingly, the Supplement's calculations for Alternatives A, B, and C, which are associated with much more extensive changes in land use than Alternative D, result in substantial decreases in total annual pollutant loads for most pollutants compared to either the baseline or the No Action/No Project ("NA/NP") alternative. Alternative D results in an increase compared to the baseline and only a slight decrease for most pollutants compared to the NA/NP alternative. (See Supplement, TRS-5, Tables S6 through S12, pp. 8-11.) It appears that the Supplement used those data that underestimate impacts rather than data that are more appropriate.

I.D Total Pollutant Loads Underestimated

The use of LACDPW's EMCs for the airport operations/airport open space land uses would have resulted in much less favorable data for the six pollutants for which the Supplement used the AAAE/ARDF EMCs, *i.e.* TSS, TP, TKN, O&G, BOD₅ and COD. We recalculated the total estimated pollutant loads for these six pollutants with LACDPW's EMCs for the airport operations/airport open space land uses for the baseline, the NA/NP Alternative and Alternatives A, B, C, and D for buildout year 2015. Pollutant loads for all other land uses were assumed to be unchanged since the Supplement's calculations for those were based on LACDPW's EMCs. (See Table 1.)

As expected, total pollutant loads (including the baseline and the NA/NP alternative) are substantially higher than those presented in the Supplement for

all pollutants. For example, the revised estimate for TSS for Alternative D in 2015 is 822,502 pounds per year ("lb/year") compared to the 434,041 lb/year calculated by the Supplement. (See Table 1 and Supplement, TRS-5, Table 12 through S12, p. 11.)

Further, where previously only five of the 24 values for pollutant loads (four Alternatives/six pollutants) exceeded the NA/NP alternative values, there are now 13 values that exceed these values. Compared to the baseline, previously only eight of the 24 pollutant load values exceeded the baseline values, now there are 16 values.

These much higher total pollutant loads have consequences for the mitigation measure. It must be demonstrated that a combination of source control, structural and treatment control best management practices ("BMPs") can reduce these pollutant loads sufficiently to result in a "no net gain" in discharged pollutant loads.

I.E Stormwater Runoff Coefficient Underestimated

The Supplement used stormwater runoff coefficients determined by a 1987 method advocated by the Federal Highway Administration ("FHWA"), the same method presented in the Draft EIS/EIR. (Supplement, p. 4, Draft EIS/EIR, pp. 24/25.) We had previously pointed out that a more recent method exists that more accurately captures local conditions, which is used by the Los Angeles County Department of Public Works ("LACDPW") and other local agencies. (2001 Fox Comments, II.G, pp. 18/19.) Use of this method results in considerably higher runoff coefficients and hence substantially greater runoff. The Supplement failed to provide an explanation on why it chose the FHWA method over the more applicable LACDPW method.

I.F Data For 1996 Baseline Year Are Inconsistent

The Supplement continues to use the year 1996 as its baseline for the hydrology and water quality analysis and maintains that hydrology results for baseline conditions remain unchanged from the Draft EIS/EIR, *i.e.* they are based on year 1996 conditions. (Supplement, TRS-5, p. 5.) Water quality results on the other hand were updated to reflect updated information, *e.g.*, average annual precipitation data now include the time period from 1948 to 2000 and, as discussed above in Comment I.C, LACDPW EMCs were adjusted to include the year 2000. The estimates of average annual pollutant loads for the baseline condition are dependent on the average annual precipitation, the EMCs, and on the various on- and off-airport land uses. According to the Supplement, the off-airport land uses had apparently already been updated for the Draft EIS/EIR to

reflect year 2000 conditions. (Supplement, Appx. S-B⁷, p. 40.) Presumably, since the Supplement did not comment on it, the on-airport land uses are still characterized for the year 1996.

This treatment of the baseline conditions is inconsistent and unacceptable. To be consistent, factors affecting hydrology, *i.e.* drainage and flood control structures, as well as on-airport land uses should have also been updated to reflect year 2000 conditions.

Here, as in the other sections, the Supplement should have used the 2000 baseline. Using a 1996 baseline for a project that will be implemented in the year 2004 is entirely inappropriate, especially considering the fact that newer data sets exist.

II. MITIGATION MEASURE REMAINS INADEQUATE

The Draft EIS/EIR proposed mitigation measure HWQ-1 to address significant water quality impacts, *i.e.* an increased load of a pollutant of concern delivered to a receiving water body by surface water runoff. This measure consists of the commitment to develop a drainage plan once an alternative is selected. The purpose of this drainage plan will be to "assess site-specific drainage flows at a design level of detail that provide adequate drainage capacity to prevent flooding." The drainage plan will incorporate BMPs "to minimize the effect of airport operations on surface water quality and to prevent a net increase in pollutant loads to surface water resulting from the selected Master Plan alternative." (Supplement, p. 4-410.) The Supplement made only minor changes to this mitigation measure.

The Supplement merely presents lists of potential methods to reduce peak flow of surface water runoff, potential measures to increase drainage capacity, and potential BMPs that could be employed to infiltrate or treat storm water runoff and dry weather flows, and control peak flow rates. The descriptions of the mitigation measures in the Supplement are too general to assure that they will actually be implemented. The measure does not establish specific targets that must be met, *e.g.*, no net increase in pollutants discharged from the site, and are not enforceable as a practical matter.

Enforceability is normally achieved by including mitigation measures in the requests for bids and resulting construction contracts, posting bonds, drawing up legal agreements, or recording conditions of approval on property

⁷ LAX Master Plan Supplement to the Draft Environmental Impact Statement/Environmental Impact Report, Appendix S-B, Existing Baseline Comparison Issues – 1996–2000, July 2003,

titles or in agency permits. None of the proposed mitigation measures include any legally binding commitments or methods to ensure implementation and enforcement.

The mitigation measure also does not specify criteria for selecting from among these various methods, measures, and BMPs. (Supplement, pp. 4-410/411.) The Supplement made no attempt to assess feasibility of any of the measures, or to evaluate their secondary impacts, thus deferring the development of the drainage plan to the future, outside of public view.

II.A Development Of Mitigation Plan Cannot Be Deferred

Rather than developing a conceptual level design for each of the proposed alternatives, as we suggested in our comments on the Draft EIS/EIR, the Supplement continues to defer the development of the proposed drainage plan until after an alternative is selected and only added the request that the plan be developed "to the satisfaction of the City of Los Angeles Department of Public Works, Bureau of Engineering." (2001 Fox Comments, I., p. 1/2; Supplement, p. 4-410.) The Supplement thus removes the review of the proposed drainage plan from public review. This approach is not permissible under CEQA and NEPA.

While it is not feasible to develop a detailed engineering design of physical facilities before an alternative is selected, it is possible to develop a conceptual level design for each alternative. This would facilitate selecting and evaluating the mitigation measures that could be used to reduce the impacts from Project alternatives.

Further, by deferring the development of the plan into the future until after the alternative is developed, secondary impacts from the mitigation measures cannot be identified, assessed and mitigated, as required. For example, the selection of Alternatives A, B, or C would involve the elimination of the Imperial water quality retention basin and require that an alternative retention and/or water quality treatment BMP be provided. (Supplement, p. 4-456.) Both the elimination of the Imperial water quality retention basin and the establishment of an alternative will result in local changes of the water quality and peak flows. It will also have construction emission impacts that have not been assessed. These secondary (or indirect) impacts of the mitigation measure need to be evaluated to understand the full impact of the selected alternative on hydrology and water quality.

II.B All Feasible Mitigation Not Required For Flows And Water Quality

We commented previously that the list of specific mitigation measures, from which a selection would be made for the drainage plan, was limited and incomplete. We recommended that the list be expanded to include the large body of Best Management Practices ("BMPs") developed by federal, state, and local agencies as well as inspection and maintenance programs. We recommended incorporating into the list all feasible measures based on the large number of manuals and guidelines that have been published. (2001 Fox Comments, p. 2.)

Aside from specifying one additional measure, *i.e.* hydrodynamic devices, the Supplement only added that "Best Management Practices (BMPs) will be incorporated to minimize the effect of airport operations on surface water quality and to prevent a net increase in pollutant loads to surface water resulting from the selected Master Plan alternative" and that "[o]ther structural BMPs may also be selected from the literature and the many federal, state and local guidance documents available." (Supplement, p. 4-410.)

This requirement does not cure the defects previously identified in the previous Draft EIS/EIR version. If the specific measures that would be implemented are not identified in the Draft EIS/EIR, the public is precluded from reviewing them. Further, if the specific measures are not identified, it is not possible to determine if the impacts have been reduced to a less than significant level. Finally, if specific measures are not identified, it is not possible to identify and assess secondary (indirect) impacts from the mitigation measures themselves. For example, impacts from building new retention basins might include local changes in water quality and peak flows, changes in water quantity of receiving wetlands, habitat changes, and construction air quality impacts.

II.C Method To Evaluate Effectiveness Not Stated

We previously commented that the Draft EIS/EIR did not specify any monitoring provisions or methods to determine the effectiveness of the above mentioned future drainage plan. We recommended that the monitoring program be described with sufficient specificity to allow a knowledgeable individual to assess its efficacy. We further recommended to establish a stormwater flow and pollutant load baseline for at least two years prior to the start of construction and to continue monitoring for at least two years beyond buildout. (2001 Fox Comments, I.C, pp. 3/4.)

The Supplement did not address this issue beyond merely adding that "LAWA will prepare a specific Standard Urban Stormwater Mitigation Plan

(SUSMP) for the selected alternative," which "addresses water quality and drainage issues by specifying source control, structural, and treatment control BMPs with the objective of reducing the discharge of pollutants from the stormwater conveyance system to the maximum extent practicable." (Supplement, p. 4-411.)

This statement does nothing to address the lack of monitoring provisions, it does not set any goals, nor does it identify how LAWA's Standard Urban Stormwater Mitigation Plan ("SUSMP") would select the BMPs or determine their efficiency.

II.D The BMP Copper Calculation Is Flawed

The Supplement added a brief discussion of storm water BMPs, presumably in an attempt to rationalize the lack of a detailed mitigation plan (Supplement, TRS-5, p. 11/12.) It attempts to "illustrate the potential to achieve no net gain in pollutant loads" by calculating the quantity of a pollutant, exemplary for total copper under Alternative A in 2015, that could potentially be removed through a retention basin – assuming a certain percentage of runoff can be diverted to the retention basin – and comparing this quantity to the estimated increase in pollutant load compared to the baseline. The calculation results in a range of total copper that could potentially be removed by a retention basin, 33 to 77 lb/year. The Supplement's estimate for the average annual copper load increase for this alternative compared to the baseline is 42 lb/year. (Supplement, TRS-5, p. 12.)

The Supplement then, without any further discussion, concludes that "it can be seen that the additional estimated average annual copper load ... resulting from construction of Alternative A could be treated so that estimated annual average baseline copper loads would not be exceeded" and that "[t]his could also be shown for other potential pollutants." (Supplement, TRS-5, p. 12.)

This conclusion is not supported by the Supplement's calculation since the amount of additional estimated average annual copper load is higher than the lower bound of the potential removal efficiency of the retention basin. While it is likely that the removal efficiency is somewhere in between the lower and the upper bound, the Supplement cannot rely on it. In this case, additional mitigation measures would have to be implemented to reduce at least another nine pounds of copper – the difference between the lower bound of the removal estimate and the additional total copper load. However, absent more detailed information on the implementation of other methods and BMPs that would remove copper, it cannot be concluded that a sufficient quantity of the pollutant can be removed to achieve no net increase.

II.E Conclusion Of Non-significance After Mitigation Not Valid

One cannot conclude that a significant impact is less-than-significant after implementation of mitigation without quantifying the impact after mitigation and then comparing the result to a significance threshold, in this case "no net increase in pollutant loads compared to the baseline." The Supplement failed to do this for any pollutant save copper. As discussed in Comment II.D, the copper analysis is flawed and does not demonstrate "no net increase". Thus, the Supplement does not demonstrate that the proposed mitigation measures reduce the impacts to a less than significant level.

III. SOME IMPACTS WERE NOT EVALUATED

III.A Dry Weather Flows Were Not Analyzed

We previously commented that the Draft EIS/EIR should have analyzed dry weather flows, *i.e.* discharge from storm drains during the dry season, but the Supplement does not contain this analysis. (2001 Fox Comments, p. 19.) Elevated total and fecal coliform levels are of particular concern in dry weather flows.

The Draft EIS/EIR describes the many sources of dry water flows but does not contain any quantitative analysis. (Draft EIS/EIR, TR6, pp. 33-34.) This is particularly problematic for Alternatives A, B, or C, which would involve the elimination of the Imperial water quality retention basin and require that an alternative retention and/or water quality treatment BMP be provided. (Supplement, p. 4-456.)

We previously commented on this lack of an analysis and noted that its reliance on existing regulations and procedures cannot be used to avoid performing a proper analysis. (2001 Fox Comment, III.A, pp. 19/20.) The Supplement does not acknowledge these comments nor does it add any additional comment.

The document should be modified to quantitatively evaluate the impacts of dry weather flows and to impose feasible mitigation to reduce the impacts to a less-than-significant level.

III.B Construction Water Quality Impacts Were Not Evaluated

Neither the Supplement nor the Draft EIS/EIR contains an analysis of the water quality impacts of Project construction. Construction of the Project would

occur over an extended period of time and affect a very large area. Construction activities are notorious for creating erosion and generating muddy turbid runoff, *i.e.* high TSS pollutant loads. The Draft EIS/EIR acknowledges that construction “could create sources of pollution that could potentially affect water quality,” yet it contains no analysis of this issue, instead arguing that following the procedures in LAWA’s Construction Storm Water Pollution Prevention Plan (“SWPPP”) for LAX would assure that these impacts would be less than significant. (Draft EIS/EIR, pp. 4-553, 4-556, 4-559.) However, it is impossible to conclude that site-specific impacts have been fully mitigated without first performing an appropriate analysis. Further, it is impossible to review a document that purports to address the issue when the document is not provided for public review.

We previously commented on this lack of an analysis and noted that reliance on existing regulations and procedures cannot be used to avoid performing a proper analysis. (2001 Fox Comments, III.A, pp. 19/20.) The Supplement does not acknowledge these comments nor does it add any additional comment.

This lack of a quantitative analysis is unacceptable under CEQA and the document must be modified to quantitatively evaluate the impacts of construction for each alternative and to impose feasible mitigation to reduce the impacts to a less-than-significant level.

HAZARDOUS MATERIALS

Los Angeles World Airports ("LAWA" or "the Applicant"), the operator of the Los Angeles International Airport ("LAX"), has published a Draft Master Plan Addendum, a Supplement to the Draft Environmental Impact Statement/Environmental Impact Report¹ ("Supplement"), and Airport Layout Plans Package on the modernization of LAX ("Project"). These documents supplement the Draft Environmental Impact Statement/ Environmental Impact Report² ("Draft EIS/EIR") and add discussion of Alternative D to the previously discussed Master Plan alternatives.

There are a number of contaminated properties in the areas that would be disturbed by construction. (Supplement, Table S4.23-1 and Figs. S4.23-1, S.23-2, S4.23-3, S4.23-4, S4.23-5.) The Draft EIS/EIR and Supplement acknowledge this contamination could result in significant impacts and recommend two Master Plan Commitments, HM-1 and HM-2, to mitigate these impacts. (Draft EIS/EIR, pp. 4-979/980 and Supplement, pp. 4-559/600.) However, the Draft EIS/EIR and Supplement fail to discuss all of the impacts of this contamination. Further, these two mitigation measures are not adequate to mitigate the impacts to a less than significant level.

These comments expand upon some of our previous comments on the Draft EIS/EIR and address new issues raised by the Supplement. (Comments on Hazardous Waste, LAX Master Plan Draft EIS/EIR (July 13, 2001) by J. Phyllis Fox, Ph.D., Attachment F to September 18, 2001 Comments Submitted on Behalf of the City of El Segundo by Shute, Mihaly & Weinberger ("2001 Fox Comments").)

I. IMPACTS NOT EVALUATED

IA Impacts Of Construction At Contaminated Sites Are Significant And Neither Adequately Analyzed Nor Mitigated

The Draft EIS/EIR and Supplement identify a number of contaminated sites and conclude that additional contamination may be discovered during construction. The Draft EIS/EIR and Supplement also admit that disturbance of

¹ LAX Master Plan Supplement to the Draft Environmental Impact Statement/Environmental Impact Report, July 2003.

² LAX Master Plan Draft Environmental Impact Statement/Environmental Impact Report, January 2001.

contaminated soils and groundwaters during construction "could pose a risk of exposure to construction workers or the environment." (Draft EIS/EIR, pp. 4-989, 4-993, 4-994 and Supplement, p. 4-608.) However, neither the Draft EIS/EIR nor the Supplement evaluates what those impacts would actually be, instead arguing without any analysis that these impacts would be fully mitigated by Master Plan Commitments HM-1 and HM-2 and existing laws and regulations.

However, as discussed in Comment II below, these measures are not adequate to mitigate significant impacts from construction at contaminated sites. Further, compliance with existing laws and regulations will not avoid adverse impacts to workers because they do not address construction at contaminated sites. HM-1 and HM-2 do not ensure that all contamination will be remediated prior to the start of construction, and they provide no means to identify previously undiscovered contamination that comes to light during construction, creating a situation in which construction workers could be adversely exposed to contaminated soils and groundwaters. Thus, significant exposures are possible and unmitigated.

In addition to the comments made on this issue in the Fox 2001 Comments, the failure to thoroughly investigate sites of known soil and groundwater contamination results in a significant impact of construction at contaminated sites.

The failure to complete remediation at construction sites and provide for safety procedures to deal with encounters with previously unidentified contamination before construction begins is amplified by the fact that many known sites within the Master Plan boundaries have yet to be characterized sufficiently for remedial measures to be selected. Table S4.23-1, Soil and Groundwater Contamination and Remediation Status, lists ten sites at which investigation of soil contamination is not completed and that are within the footprint of all four alternatives. An additional five such sites are within the footprint of one or more of the alternatives. The same Table lists four sites at which investigation of groundwater contamination is not completed and that are within the footprint of all four alternatives. An additional three such known groundwater contamination sites are within the footprint of one or more of the alternatives. The presence of known, but uncharacterized soil and groundwater contamination increases the probability of uncontrolled encounters by workers during construction activities.

I.B Significance Thresholds Not Adequate

In addition to the comments made on this issue in the Fox 2001 Comments, the significance thresholds are not adequate in yet another respect.

The fourth threshold of significance listed in the Supplement, "Contamination of soil or groundwater or prevention of cleanup of sites that are *currently undergoing soil or groundwater remediation*" is also inadequate. (Supplement, p. 4-599.) Soil or groundwater contamination caused by the Master Plan would be significant if it would potentially frustrate future investigation efforts or foreclose remedial options that future investigation efforts may find would be most effective. The fourth threshold of significance should be reworded to be "Contamination of soil or groundwater, prevention of cleanup of sites that are currently undergoing soil or groundwater remediation, or construction in an area of known soil or groundwater contamination for which investigation and remedy selection are not yet accomplished."

II. MITIGATION MEASURES ARE NOT ADEQUATE

The mitigation measures recommended in the Draft EIS/EIR and Supplement are not adequate to protect construction workers at or near contaminated sites, for the reasons presented in the Fox 2001 Comments. In addition, these mitigation measures are not adequate to ensure thorough remediation of soil and groundwater contamination, particularly where investigations of known contamination are not yet completed.

An environmental site inspector, reporting to the City and oversight agency, had to be present during construction to detect previously undiscovered contamination.

The Draft EIS/EIR's and Supplement's analyses of contaminated properties are plagued with circular reasoning that fails to mitigate significant impacts. The following expands the significance of this circular reasoning.

Draft EIS/EIR and Supplement admit that known contamination poses a risk to construction workers and the environment. As mitigation, they recommend mitigation measure HM-1, which requires that existing soil or groundwater remediation efforts at contaminated sites be remediated prior to the start of construction. This requirement appears to apply only to known contamination sites at which the requisite investigation has occurred to support beginning a soil or groundwater remediation effort in the first place. Where such investigation has not of yet occurred, or been completed, HM-1 appears not to apply. Moreover, a careful reading of this measure indicates that remediation need not be completed prior to construction if it is "not possible," which leads

back to the original impact, *sans* mitigation. The Draft EIS/EIR and Supplement neglect to analyze the impacts if remediation is not possible or has not started because the remedial measure has yet to be selected.

II.A. Mitigation Measure HM-1

HM-1 is inadequate in two fundamental areas. First, it is deficient in the way it attempts to protect the continued effectiveness of existing remediation efforts. Second, it does not provide for completion of investigation at sites of known contamination prior to beginning construction. The first of these areas of inadequacy is thoroughly discussed in the Fox 2001 Comments.

The second fundamental deficiency of HM-1 is its failure to require completion of investigations at known contamination sites prior to construction. Because the investigation of known soil and groundwater contamination is incomplete, and in some instances not even begun, remedial alternatives for the most effective remediation may be foreclosed. Soil or groundwater contamination that becomes covered by the Project's runways or buildings may be difficult, and sometimes impossible, to clean up as thoroughly as before construction occurs.

Unfortunately, Master Plan Commitment HM-1 is silent with regard to known contamination for which remedial efforts have yet to be identified because investigation has yet to begin or is incomplete. By its very nature, Master Plan Commitment HM-1 as currently worded could not assure effective remediation after Project construction, unless the investigation of soil and groundwater contamination were completed so as to enable selection the optimal remedial alternative. Construction in areas of known soil or groundwater contamination that have not been fully investigated is a significant impact not acknowledged in the Supplement. HM-1 should be revised to provide for acceleration of environmental investigations at and near construction sites before any construction occurs that could either hinder investigation or install Project facilities that render a preferred remedial alternative less effective.

In sum, investigation and remediation of hazardous waste contaminants is nearly always completed before the start of construction. Master Plan commitment HM-1 should be modified to explicitly require the investigation and remediation of all contaminated properties prior to the start of construction.

II.B. Additional Mitigation Measures

The above comments, and those discussed in Fox 2001 Comments, identify potentially significant impacts that have not been either discussed or

mitigated in the Draft EIS/EIR and the Supplement. The Supplement should be revised to include analyses and recommend mitigation measures for these impacts. In addition to the Fox 2001 Comments' commonly required measures that are feasible and should be included, the following mitigation measure should be required:

- Construction should not begin at any site of known soil or groundwater contamination until investigations and remedy selection have been completed and approved by the appropriate regulatory agencies.

COMMENTS

**2003 LAX MASTER PLAN ADDENDUM & SUPPLEMENT
TO THE DEIS/EIR**

Prepared for Shute Mihaly and Weinberger

**By
A. Kanafani**

**Berkeley, California
November 2003**

INTRODUCTION

The following comments analyze several elements of the 2003 LAX Master Plan Addendum (Addendum) and Supplement to the DEIS/EIR (Supplement). We have conducted an extensive analysis of the gate capacity of Alternative D, which is summarized in these comments and more fully documented in the attached report, "Capacity Analysis of Aircraft Gate Positions", (Appendix A). The comments below also discuss additional aspects of Alternative D relating to its physical capacity, including airfield configuration and sequencing of the Master Plan. In addition, we have analyzed the proposed alterations to the Runway 25 complex. We have identified numerous uncertainties regarding the proposed changes to this southern runway complex and concluded that additional information must be provided before we can fully evaluate its effects on El Segundo.

1. ALTERNATIVE D CAPACITY ISSUES

The Master Plan Addendum's Alternative D proposes to limit LAX to approximately 78 MAP by limiting the total number and size of gate positions to a figure that is below the other alternatives, and below the current values. This, 78 MAP is a limit on passenger traffic; it does not limit the total number of aircraft operations. According to the Addendum and the Supplement, the total number of aircraft operations remains about the same for Alternative D as for Alternative C and the No Action/No Project Alternative. The Addendum's stated conclusion that Alternative D will serve no more than 78 MAP, i.e., substantially less than the 89 MAP served by Alternative C, is based on the assumption that by limiting the number and size of gates, it will force airlines to make specific anticipated adjustments to their markets and to shift services around between categories (international, domestic air carrier, commuter, etc.), and between aircraft types, and between airports in the Southern California region, which, according to The Addendum's projections, would result in approximately the target number of passengers served. The published documents provide no discussion on specific actions LAWA or other regional authorities propose to take in order to cause such market-driven adjustments to occur, nor do they provide any meaningful basis for concluding that The Addendum's assumptions are accurate or that the airlines would make the assumed adjustments to types of services offered. This is particularly problematic since the airfield and other elements of the airport under Alternative D have capacities that exceed the target 78 MAP.

The following sections summarize our analysis of capacity issues related to the airfield configuration, terminal and gate positions. *Our conclusion, based on this analysis and on our full analysis of the gate capacity of Alternative D (Appendix A to this report), is that the gate positions as currently proposed by Alternative D do not limit future passenger levels to 78 MAP, especially since the airfield and other airport elements can accommodate larger numbers.*

1.1 Airfield Capacity

The airfield improvements proposed in Alternative D include runway relocation to increase the distance between parallel runways as well as runway length extensions. The increased separation allows the addition of centerline parallel taxiways between each pair of runways (24L/R and 25L/R). While these improvements are aimed primarily at enhancing runway safety by improving the runway crossing and reducing the potential for runway incursions, they will to some extent reduce delays, improve the overall operation and thus have a generally positive impact on runway capacity.

The DEIS/EIR Supplement (see p. ES 1-3) uses the concept of practical capacity as constraining the traffic at the airport, defining it on the basis of flight delays, expressed in minutes of delay per operation. But then the analysis in the Supplement goes on to show that Alternative D will have lower delay rates. This means that Alternative D will provide an increase in practical capacity, using the Master Plan's own definition. Fig. E-17 of the Addendum, Appendix E, shows this reduction in average delay for Alternative D compared to both the NA/NP alternative and to Alternative C.

The table below lists the improvements to the airfield planned in Alternative D and as shown in Table ES-2 of the Supplement. Comparing the various alternatives, each of these improvements has an effect on capacity, and that effect can be either positive or negative. From the comparisons available it is clear that all the airfield improvements in Alternative D enhance capacity over the baseline, leading to the conclusion that the airfield configuration proposed in Alternative D will have a capacity that is greater than, or at least equal to, that of the existing baseline or to the NA/NP alternative

Furthermore, based on The Addendum's analysis Alternative D even appears to have a capacity equivalent to, and possibly even higher than, Alternative C. The airfield analysis shown in Tables E-4 through E-7 of the Addendum, Appendix E, shows Alternative D operating with an all-weather average peak hour throughput of 141 operations as compared to 138 for Alternative C and 140 for the NA/NP alternative.

Based on this comparison, the airfield configuration proposed in Alternative D does not preclude traffic from reaching levels well beyond the baseline volumes, and can accommodate levels that exceed those projected for Alternative C of the Master Plan.

Airfield Improvements and Capacity Comparisons

Existing Baseline	Master Plan Alternative C	Alternative D	Effect on Airfield Capacity of Alternative D Compared to:	
			Baseline	Alt. C
Outboard North Runway 24R				
8,925 ft.	9,400 ft	10,420	≥	≥
Inboard North Runway 24L				
10,285 ft.	12,000 ft	11,700	≥	≤
	Shorten west end by 2,900 ft.	Relocate 340 ft. south	≥	=
	Extend 2,900 ft. east	Extend 715 ft.	≥	=
	Add centerline taxiway	Add centerline taxiway	≥	=
Outboard South Runway 25R				
12,091 ft.	12091 ft.	12091 ft.	=	=
Outboard South Runway 25L				
11,096	11,096	11,096	=	=
	Move Runway 50 ft. South	Move Runway 50 ft. South	≥	=
	Add centerline taxiway	Add centerline taxiway	≥	=
		Add cross-field taxiway, N-S	≥	≥

1.2 Terminal and Gate Position Capacity

The LAX Master Plan Addendum proposes a configuration for Alternative D that includes 153 nominal aircraft gate positions, and a distribution of gate sizes that results in about 179 narrow body equivalents (NBEG). However, neither the Addendum nor the Supplement to the DEIS/EIR contains a capacity analysis of the proposed terminal and gate position system. Instead, the Addendum calculates a flow of 78.8 million annual passengers (MAP) on the basis of a series of market assumptions and forecasts.

Our review and analysis of the proposed terminal and gate configuration for Alternative D leads to the conclusion that the capacity of the system exceeds 78 MAP, and is close to 87 MAP. (See Attachment A to this Report, Capacity Analysis of Aircraft Gate Positions.) The analysis on which this capacity estimate is based accepts the majority of the assumptions of the Master Plan and is considered a fairly conservative estimate of the system's ability to handle traffic.

The Addendum's calculation of passenger traffic flow is based on a number of market assumptions. These assumptions do not represent a capacity analysis of the gate positions, but an estimate of what traffic volumes might be under assumed market conditions. We consider these market assumptions to be fairly conservative, and result in an underestimation of possible traffic volume. The traffic volumes used in the Addendum cannot be used as a representation of the capacity of the system.

In the following paragraphs, we list the assumptions used by the Addendum and we provide comments on them, pointing out discrepancies, errors, and inaccuracies. The assumptions of the Addendum that underlie the estimation of traffic are summarized in Table 1 below, which shows the excerpts from Table 3.3-1 of the Master Plan Addendum, comparing the NA/NP alternative with Alternatives C and D. (Table 1 here contains corrections to some numbers that were erroneous in the Addendum)

Table 1. LAX Master plan Assumptions for Alternatives

Alternative	NA/NP	C	D
Annual Passengers	78715200	89553200	78864100
Annual Operations	712500	714000	713100
Design Day Operations	2058	2058	2058
Design Day Passengers	262329	298588	262758
Design Day Enplanements per Departure	127.47	145.09	127.68
Annual Enplanements per Departure	110.48	125.43	110.59
Annual Conversion Factor	300	300	300
Nominal Gates 2015	163.00	168.00	153.00
NBEG 2015	188.20	222.20	178.90

1. Total Airport Traffic

As seen in Table 1 above, the Addendum indicates that Alternative D is designed to handle about the same total annual and Design Day aircraft operations in 2015 as the No Action/No Project Alternative and Alternative C. Despite this, the Addendum concludes that annual passenger flows will differ dramatically between the alternatives. This is based on assumed distributions of these operations among types of operations, aircraft, and gate position sizes. The basic premise of the Addendum is that airlines will respond to the number and size of gates by downsizing fleets and will thereby end up carrying fewer passengers per operations. The Addendum quantifies these effects by making extensive assumptions regarding airline operation and markets. There is no justification or validation of the vast number of market assumptions used in the Addendum to arrive at the traffic flow numbers presented. A detailed review of some of these assumptions also raises doubt about their viability. For example the Addendum predicts that the number of domestic air carrier passengers will actually drop at LAX between 2000 and 2015 (from 47 MAP to 45 MAP). Some of that drop is taken up by growth in commuter passengers (about 0.7 MAP). The implication is that the rest of the traffic demand will move to other regional airports. There is no reason to believe that this shift will occur, especially in the absence of specific policies that make it happen, and certainly not with the proposed number and configuration of gate positions proposed in Alternative D.

2. Fleet mix and aircraft sizes

The Addendum makes assumptions about the fleet mix that it considers to be a market response to the limited number and size distribution of gates provided in Alternative D. The Addendum further assumes that each aircraft carries what it refers to as a "typical" number of seats.

There are several assumptions regarding fleet mix used that we believe are questionable. The first concern is with the accuracy of assumed seating for each aircraft considered in the analysis. In the attached capacity report we show that the assumed aircraft seating sizes are not realistic for capacity comparison, and while they might reflect current market conditions, they do not reflect what the practical capacity of gates are, especially given the current developments in the fleet and the types of aircraft that airlines using LAX are ordering.

The second concern deals with some of the aircraft types used, where older versions are retained in the analysis and some of the newer aircraft versions are not taken into account. For example, B-737-800 and B-737-900, are overlooked even though a fair number of those aircraft have been ordered by the major airlines operating at LAX. These types have significantly higher number of seats compared to the earlier versions of the same type. Also, the Master Plan's fleet mix includes some of the older aircraft types that are likely to be phased out of the operations by 2015 (i.e. F-100, ATR-42), either because they are fairly old and not compatible with the noise (and other) standards, or because they have already been out of production for some time (examples include F-100, F-70, ATR-42).

The GA, military, cargo and air carrier fleet mix used in the Alternative D is not clearly described in the Addendum. In many places the Addendum refers to the fleet mix assumptions of LAX Master Plan Draft, but the data and information differ between the two, and there are no explanations of these differences.

3. Traffic Operations by Type of Service

The Addendum assumes a mix of total design day operations by carrier type: domestic, international, Hawaiian, and commuter. These operations split assumptions are shown in Table 3.3-1 of the Addendum. The Addendum bases these assumptions on the following market analysis as stated (Addendum Section 3.3.3 Air Service Changes):

- *“Commuter operations would likely be reduced from 1996 levels, consistent with the forecasts for No Action/No Project and Alternative C, in order to maximize the number of passengers that could be served with a limited number of operations. It is also projected that some of the forecast commuter O&D demand would be served by domestic air carrier flights.*
- *Domestic air carrier connecting passengers would decrease from 2015 forecast levels to reflect the projected loss of connecting passengers from commuter flights.”*

According to these assumptions, one would expect the number of commuter operations not to be as high as it is projected in Alternative D. So while all three alternatives (NA/NP, Alternative C and Alternative D) are projected to show a drop in commuter operations from the 1996 level of 644 during the design day, Alternative D seems to have dropped the least. In fact, Alternative D forecasts that the commuter traffic will actually grow from today’s level. In Table 3.3-1 of LAX Master Plan Addendum we see that there were 644 commuter operations in 1996, then 474 commuter operations in 2000. Alternative D assumes that these operations will grow to 532 in 2015, which does not agree with the Master Plan assumptions. The table below shows the Addendum’s questionable assumption that commuter operations in Alt D will exceed the NA/NP alternative.

Commuter Operations, Design Day and Annual Passengers

	1996 Actual	2000 Actual	2015 NA / NP	2015 Alt. D
Operations	644	474	467	532
Passengers	7595	8232	10147	11937
Total Passengers	186512	215645	262329	262758
Percentage	4.1%	3.8%	3.9%	4.5%
Annual Passengers	2759991	2918282	3115400	3664900
Annual Total Passengers	57974559	67303182	78715200	78864100
Percentage	4.8%	4.3%	4.0%	4.6%

4. Seasonal patterns

Another of the Master Plan assumptions that we believe is flawed is the adopted Annual Conversion Factor of 300. (Annual Conversion Factor = Annual Passengers/Design Day Passengers). The LAX Draft Master Plan correctly assumes that as traffic grows in the face of limited facility expansion, de-peaking of both operations and passengers will occur. This should result in a rise rather than a decline of the Annual Conversion Factor. Table 2 below shows the actual operations and Annual Conversion Factors for 1996 and 2000, and the Addendum's forecasted values for 2015. We can see that even in year 2000 when the number of operations declined, the Annual Conversion Factor was 312. In 1996 it was 310. If alternative D involves de-peaking due to the capacity constraint then we should expect these factors to increase and not to decrease to the 300 level assumed in the Master plan.

Table 2. Annual Conversion Factors

	Design Day Passengers	Annual Passengers	Annual Conversion Factor	Design Day Operations	Annual Operations	Annual Conversion Factor
1996 Actual	186,512	57,974,559	310.83	2055	712,206	346.57
2000 Actual	215,645	67,303,182	312.10	2054	710,791	346.05
NP Action 2015	262,329	78,715,200	300.06	2058	712,500	346.21
Alternative C 2015	298,588	89,553,200	299.92	2058	714,000	346.94
Alternative D 2015	262,758	78,864,100	300.14	2058	713,100	346.50

It is also curious that the same conversion factor of 300 is used for all alternative A through D and the NA/NP alternative. If there were a basis for changing the factor depending on market response to the different alternatives, then one would have expected it to vary among such vastly differing alternative as A and D. But it does not. Nor do the annual factors used to convert design daily operations, which appear to be the same for all alternatives, and the same for the base years of 1996 and 2000 as well as 2015. The Addendum's estimate of annual passenger flows as based on these conversion factors is therefore considered questionable and not a sound basis for estimating system capacity, not in the terminal, and not in the airfield for that matter.

5. Mix of Gates and Computation of Narrow-Body Equivalent (NBEG's)

The Addendum uses the concept of narrow-body equivalents (NBEG's) to characterize the size of different gate types. This is a sound concept in principle, but needs to be used with caution when analyzing the capacity of a gate position system. The reason is that for the same wingspan, or gate position size, aircraft come in a fairly wide

variety of seating configurations. A one narrow-body equivalent gate, for example, can accommodate aircraft with seating configurations as low as 100 and as high as 200. Furthermore, the capacity can be altered significantly by converting smaller gates into larger ones, losing numbers of gates, but gaining seating capacities and passenger flows.

It is therefore important from the capacity control perspective to ensure that a gate mix proposed and approved in the Master Plan not be altered, even if the total number of NBEG's remains unchanged. We note that there are some mistakes in the computation of the number of NBEG's as presented in the Addendum. These are described and corrected in the attached capacity analysis report.

1.3 Terminal Building Square Footage

There are discrepancies in the total available square footage ASF of the terminal building in Alternative D as presented in various locations in the Addendum and the Supplement. Figures of 6.55 million available square feet appear commonly, but so do other figures such as 6.8 million in Table S3-2 and 7.24 million in the Land Use analysis. THE ADDENDUM needs to clarify the actual figures envisaged in the Master Plan.

In any case, assuming here that the smallest of the figures that appear, 6.55 million sq. ft. is the correct one, there remains the question as to why this figure is needed. This figure is significantly higher than that of the NP/NA alternative, which has 3.99 million sq. ft. and they are both presumably serving presumably the same traffic volume. While some of that difference can be explained by the increased security requirements that are accommodated in Alternative D, the total figure remains unexplained. The same is true of the available square footage for gate lounge areas, which also exceed the figures for the base NP/NA alternative. The available square footage in the terminal system in total, and related to annual passenger volumes is compared in the table below for the three alternative, NP/NA, C, and D.

Comparison of Terminal Space Available in the Various Alternatives

Alt.	Total Terminal Sq. Ft.	Gate Lounge Area Sq. Ft.	Annual Pax per Lounge Sq. Ft.	Annual Pax per Terminal sq. ft.
NA/NP	3,997,700	360,000	218.65	19.69
Alt. C	7,319,000	518,000	172.88	12.24
Alt. D	6,550,000	416,000	189.58	12.04

This comparison raises the question as to why Alt D enjoys such a significantly higher level of service than the others. The increased terminal size would be consistent with an airport serving more than 78 MAP. A reduction in terminal square footage from the proposed major increase should be considered as a secondary means of ensuring that passenger levels under Alt D do not exceed the asserted goal of 78 MAP.

1.4 Airport parking

It is unclear why Alternative D provides a public parking capacity similar to Alternative C, when the latter is planned for a much higher level of traffic. The Addendum shows Alt. D with 35,002 stalls compared to 35,636 for Alt. C and 33,926 for the NA/NP alternative. If Alternative D has a capacity of 78 MAP, then the amount of parking provided should be less than that required for Alternative C, which is designed to serve 89 MAP. An airport whose capacity is limited to 78 MAP would generate less congestion and landside traffic, so that the amount of parking should also be reduced.

1.5 Additional Concerns Related to Capacity and Traffic Assumptions

Discrepancies in Air Traffic Assumptions Used in Noise Analysis:

Table S7 of S-C1. *Supplemental Aircraft Noise Technical Report* shows the 2015 Average Annual Day Operations and Fleet Mix for the Alternative D. The fleet mix used in this table differs from that used in the Master Plan Addendum Fleet Mix. There are several aircraft in the Table S7 that are not used in the Design Day schedule of the Master Plan Addendum: Boeing 717, British Aerospace 146, Challenger 601, Learjet 35, Fairchild SA227. There needs to be an explanation as why these aircraft types are used here and whether they represent others used in the rest of the Addendum as equivalent noise generators. Moreover, it is said that the SIMMOD outputs are used to build the input for the noise model. Presumably these SIMMOD outputs were also used to load the airfield and the gate positions, so there needs to be a clarification of these variations in fleet mix and of any necessary adjustments to the noise analysis that may result.

Another inconsistency is about the total number of the operations considered in the Average Annual Day. The total number of operations is stated as 2121, but it is actually 2123. Even so, if this is the Average Annual Day, then if we multiply this number by the number of the days in the year we should get the number of Annual Operations. In both cases (of 2121 and 2123 operations) the yearly number obtained is lower than the number of Annual Operations of the Alternative D for the year 2015, which is shown in the Table below.

**Comparison of 2015 Annual Operations
Used in Master Plan Addendum and Noise Analysis**

Alt. D Annual Operations	784,000	
Figures Used in Noise Analysis	Average Annual Day Operations	Corrected Average Annual Day Operations
	2121	2123
	774165	774895

2. The Sequencing of the Master Plan

The Addendum describes a phasing scheme for the development of Alternative D. The scheme is far too lumpy and does not illustrate the evolution of provision of airport elements in sufficient detail to ascertain capacity and other operational impacts at the intermediate stages to 2015. The proposed phasing does not guarantee that at some transitional phase during build-out of this plan, e.g. between phases II and III, the availability of gate positions and terminal facilities will not exceed the amount that limit the capacity to 78 MAP. For example, the phasing plan should ensure that opening of the West Terminal, in Phase III should not proceed before the decommissioning of the North Terminal elements.

The current phasing shown in the Addendum (sect. 2-10 of the Addendum) shows the construction of the West Satellite Concourse as occurring during phase II. The demolition of part of TBIT building and the conversion of the north terminals to a linear facility occur in phase III. Should there be a period between the completion of phase II and the start of Phase III, such a period would entail a system with a much higher capacity than intended.

This is especially true since there is no mention in the sequencing plan of the point in time at which the remote gate positions will be eliminated. If the conditions that permit capacity to exceed 78 MAP are to never arise, then a clear time plan of when the remote gate positions will be decommissioned and eliminated.

Addendum should therefore be modified to provide a very specific step-by-step phasing that would ensure that such a violation does not become possible.

3. The Runway 25 Complex

According to the text in the Addendum the proposed modifications to the runway 25L/R complex entail the relocation of runway 25L "approximately 50 ft. south of the existing runway centerline" and the insertion of a 11,096 ft. taxiway centered between the two runways 25L and 25R. No other modifications of this runway system are described in the available documents, although the plans and drawings show additional modifications such as the introduction of high-speed exit taxiways to connect the inserted center taxiway to the two runways. Although it is not described in the text, some of the drawings show that the southern taxiway (Taxiway A) will also be shifted south, presumably in order to maintain its current 500 ft. separation to runway 25L. The following comments discuss the gaps in the THE ADDENDUM'S analysis and the need for additional information and clarity regarding the proposed reconfiguration of the southern runway complex.

- Presumably the (approximate) 50 ft shift is 55.42 ft., which is the shift needed to provide space for 400 ft. separation between the center taxiway and the two runways 25L And 25R. The EIS/EIR should be corrected to include the correct number of feet of intended shift of runway 25L.
- There is no reason why taxiway A needs to move south in order to maintain its 500 ft. distance from runway 25L, since the remaining 444 ft. separation is adequate and exceeds the 400ft. separation used for the center taxiway. THE ADDENDUM needs to clarify this and to confirm that taxiway A will not be moved.
- There is no clear description in the Addendum of any further modifications to taxiways, especially any possible extensions to Taxiway A. The Addendum needs to clarify that under Alternative D the need for an end-round taxiway is eliminated and that no further westward extension of Taxiway A will be made. In the same vein, there should be no need for the taxiway bypass to connect between A and B Taxiways.
- The documents do not provide adequate analysis comparing the “centerline taxiway” alternative proposed for this runway complex and the alternative of continuing the use of left exits from runway 25L with an end-round taxiway back to the terminal area. Such a comparison, especially from the point of view of noise impacts, is critical to provide a meaningful evaluation of the noise impacts of the reconfiguration on the City of El Segundo and its residents. A published study by NASA Ames [CITE] investigates air traffic control procedures necessary to reduce runway incursions with and without the southward shifting of runway 25L but does not address the issue of noise impacts.
- While the insertion of a center taxiway between the two runways 25L and 25R may be a desirable action from the point of view of airfield operations and safety, it must be evaluated in the context of a comparative noise analysis analyzing this option and the end-around option, along with the development of the appropriate noise mitigation measures specifically designed to deal with the impact of the shifting of the runway southward on the communities immediately to the South of the airport.
- With the proposed modification in Alternative D the need to use Taxiway A for exits of aircraft landing on Runway 25L will be reduced greatly, especially after the removal of the remote gate pads in the Northwestern portion of the airfield. LAWA should adapt the taxiway system loading accordingly to ensure minimal use of this taxiway, in order to minimize its noise impact on the surrounding communities.
- Temporary use during the first phase of the plan by new large aircraft (NLA) runway 25L and the left exit into taxiway A should be restricted in order to minimize the noise impact to the south of the airport.

Conclusion regarding the Runway 25R/L Complex

Based on the publicly available documents, there is not a sufficient basis for favoring the centerline taxiway configuration of the southern runway complex, especially from the perspective of the communities south of the airport. Additional detailed analysis of the noise impacts, the operational characteristics, and the engineering requirements, is needed. Of particular importance is the articulation of specific mitigation measures that are necessary to compensate for the noise impacts.

APPENDIX A

CAPACITY ANALYSIS of AIRCRAFT GATE POSITIONS

**Los Angeles International Airport
Master Plan Alternative D**

1. INTRODUCTION

The following is an analysis of the annual passenger capacity of the aircraft gate position system as proposed in Alternative D of the Los Angeles International Airport Master Plan Addendum of July 2003. The analysis is limited to a study of the capacity of the gate configuration to serve passengers, and does not, for purposes of this analysis, dispute the market-based forecasts and assumptions of the LAX Master Plan Addendum (Addendum).

Alternative D as presented in the LAX Master Plan Addendum has a stated goal of limiting the annual capacity at LAX to about 78 million passengers. It proposes to accomplish that by limiting the number and size distribution of aircraft gate positions to 153 gate positions and a corresponding 178.9 narrow body-equivalents (NBEG's). The Addendum does not include a capacity analysis of the gate configuration proposed, showing how it can limit the traffic volume to about 78 MAP. Instead it contains a market analysis based on a set of assumptions regarding how airlines might adjust to the proposed gate positions provided by shifting traffic among categories (international, domestic air carrier, commuter, etc.), by shifting the fleet mix, and by diverting traffic to other regional airports. The analysis presented here calculates the annual passenger capacity of the proposed gate positions. It shows that the capacity significantly exceeds 78 MAP.

2. REVIEW OF THE ADDENDUM'S DESIGN AND MARKET ASSUMPTIONS

The LAX Master Plan Addendum calculates a flow of 78.8 million annual passengers (MAP) on the basis of a series of market assumptions and forecasts. Most of these assumptions are used in the capacity analysis conducted here in order to ascertain the capacity of the system, as designed and envisaged in the Master Plan Addendum. This does not mean acceptance of these assumptions. The assumptions and how they are treated in this capacity analysis are listed below:

1. *Annual & Design Day Aircraft Operations:* The Addendum assumes that Alt. D will handle approximately the same number of annual passenger operations and the same number of design day passenger operations as Alternative C and the No Action/No Project Alternative. These forecast numbers are not modified by this capacity analysis. They are shown in Table 1 below.
2. *Fleet Mix and Aircraft Sizes:* The Addendum makes assumptions about the fleet mix that are considered to be the airlines' response to the number and size distribution of gates provided in Alternative D. In addition each aircraft is assumed to carry a "typical" number of seats. The Master Plan's fleet mix assumption is shown in Table F-9 of LAX Master Plan Addendum. The aircraft size ranges assumed in the Master Plan are shown in Table IV-2.3 of LAX Draft Master Plan.

The fleet mix forecast is not modified in this capacity analysis. However, the aircraft seating capacities are revised on the basis of a review of actual seating configurations used by airlines using LAX, seating capacity ranges as offered by the

manufacturers, and seating configurations of aircraft currently on order by airlines using LAX. This is described in more detail further on.

3. *Operations By Type of Service:* The Addendum assumes a mix of the total Design Day Operations by service type: air carrier, international, Hawaiian, and commuter. The operations split assumptions in the Master Plan are shown in Table 3.3-1 of the LAX Master Plan Addendum. The Addendum forecasts a drop in air carrier operations and an increase in commuter operations between the base year and 2015. Although questionable, these market forecast assumptions are retained in the capacity analysis. They are discussed again in the next section.
4. *Load Factors:* The Addendum projects the load factors by carrier type and uses them to convert design day operations and aircraft sizes to passengers. Forecasted load factors for year 2015 are shown in Table IV-2.8¹. Projections are made by type of operation (air carrier, international, Hawaiian, commuter), and a presumably weighted average of all commercial operations is also used. The load factor assumptions and calculations found in the Addendum are not questioned and are used in this capacity analysis. A sensitivity analysis is made to show the range of capacities that result from the range of load factors used in the Addendum.
5. *Seasonal Patterns:* The conversion of the Design Day Operations and passenger flow to annual figures is based on the assumed annual conversion factors that are intended to reflect seasonal variations in traffic demand. Annual Conversion Factor of 300 is inferred from Table 3.3-1 of the LAX Master Plan Addendum. This factor is used to calculate the Annual Passengers by multiplying the Design Day Passengers with the Annual Conversion Factor. Design day flows are considered the average weekday of the peak month. Wednesday in August is used by the Master plan. The Addendum uses a conversion factor of 300 to convert the Design Day Passengers to Annual. It uses a factor of 346 to convert Design Day Operations to Annual Operations. These same factors are used for all the alternatives of the Master Plan: NA/NP, A, B, C, and D. They differ from the historic and current factors at LAX in one important way, and that is the current and recent historic figures for passenger ratios at LAX have been consistently around 310. The implication of the Addendum's assumption that the capacity constraint will cause traffic peaks to spread rather than accentuate is that these factors should rise and not decline. Therefore the conversion factor of 300 for passengers is considered wrong and is replaced by the more correct value of 310 for this capacity analysis. A sensitivity analysis is used to show the implication of the de-peak assumed in the Addendum by considering a range from 300 up to 320. The current, histories, and assumed values of these conversion factors, for both passengers and operations are summarized in the next section.

¹ According to the LAX Master Plan Addendum, the load factors and aircraft size assumptions were taken from Chapter V of Master Plan, but that information is not available in Chapter V, so we assume that the information from Chapter IV is used.

6. *Mix of Gates*: The Master Plan Addendum's gate mix for Alternative D is shown in the Table E-2. This mix results in a ratio of 1.16 between gates and narrow body equivalent gates NBEG's. (153 gates = 178.9 NBEG's). The capacity is estimated for the gate mix as given in the Addendum.
7. *Flight Schedules and Gate Position Loading*: The flight schedule is shown in Table F-9 of the Addendum. This assignment represents a certain gate position loading and implies a certain level of gate utilization. The capacity analysis presented here uses this assumed loading and schedule and does not question whether the gate utilization level achieved from the assignments can be increased, which would increase the capacity. By using the schedule used in the Addendum this analysis also implicitly accepts the daily peaking patterns assumed in the Master Plan.

2.1 Summary of the Master Plan Assumptions

Table 1 below shows excerpts from Table 3.3-1 from the Addendum, comparing the NP/NA, with Alternatives C and D. This table contains corrected numbers of NBEG's as obtained from Table V-3.3 (Lax Draft Master Plan) and Table 2.2-3.²

Table 1. LAX Master Plan Assumptions for Different Alternatives

Alternative	NA/NP	C	D
Annual Passengers	78715200	89553200	78864100
Annual Operations	712500	714000	713100
Design Day Operations	2058	2058	2058
Design Day Passengers	262329	298588	262758
Design Day Enplanements per Departure	127.47	145.09	127.68
Annual Enplanements per Departure	110.48	125.43	110.59
Annual Conversion Factor	300	300	300
Nominal Gates 2015	163.00	168.00	153.00
NBEG 2015	188.20	222.20	178.90

It should be noted, again, that as seen in Table 1, the LAX Master Plan Addendum assumed that Alternative D is designed to handle about the same total Annual aircraft Operations and Design Day Operations in 2015 as alternatives NA/NP and C. The difference in the annual passenger flow between these alternatives is attributed to the assumed distributions of these operations among types of operations, aircraft, and gate position sizes. Again, the basic assumption is that by limiting the number and size of gates, airlines will

² There are several mistakes concerning the number of NBEG's in the original report:

- The number of NBEG for existing gates in 2000 from Table 2.2-1 of LAX Master Plan Addendum is not calculated properly. The number of existing gates is 165 and according to the gate mix (Table 2.2-3 of LAX Master Plan Addendum) and the conversion table (Table IV-4.3 of the LAX Draft Master Plan) it is not 184.6, it is 190.9.
- Also, in Table V-3.3 of LAX Draft Master Plan, the number of NBEG for the NA/NP Alternative is stated to be 203.4, which is not the case if the gate distribution is the one shown in the Table 2.2-3 of Lax Master Plan Addendum. The correct number should be 188.20 instead.

respond by downsizing fleets and will thereby end up carrying fewer passengers per operation.

Design-Day to Annual Conversion Factors: As mentioned earlier, the number of annual passengers in Alternative D is also brought to 78 million by using an Annual Conversion Factor (ratio of annual number to design-day number) of 300, which is lower than the numbers observed at LAX today. Table 2 shows the actual 1996, 2000 and the forecasted values.

Table 2. Annual Conversion Factors

	Design Day Passengers	Annual Passengers	Annual Conversion Factor	Design Day Operations	Annual Operations	Annual Conversion Factor
1996 Actual	186,512	57,974,559	310.83	2055	712,206	346.57
2000 Actual	215,645	67,303,182	312.10	2054	710,791	346.05
NP/NA 2015	262,329	78,715,200	300.06	2058	712,500	346.21
Alternative C 2015	298,588	89,553,200	299.92	2058	714,000	346.94
Alternative D 2015	262,758	78,864,100	300.14	2058	713,100	346.50

One of the assumptions in the Master Plan is that the de-peaking of both operations and passengers will occur, which should result in a rise rather than a decline of the Annual Conversion Factor. We can see that even in year 2000 when the number of operations went down, the Annual Conversion Factor was 312. In 1996 it was 310. If Alternative D involves de-peaking due to the capacity constraint then we should expect these factors to increase.

3. CAPACITY ANALYSIS

Two methods are used to calculate the capacity of the gate position system as proposed for Alternative D. The first is an aggregate method based on the Addendum's projection of operations by service type and using the Addendum's fleet assumptions of the service type. The second more detailed analysis is based on the Addendum's projected flight schedule and gate assignment on an aircraft by aircraft basis. In both cases the Addendum's assumptions and forecasts are treated as described above. Aircraft seating sizes and Annual Conversion Factors are adjusted as described before, and load factors are assumed as in the Master Plan. Both of these methods yield similar results, and also corroborate the flow numbers estimated in the Addendum under the Addendum's assumptions.

3.1 PRELIMINARY CAPACITY ANALYSIS

A preliminary capacity analysis is shown in Tables 3 and 4. In this method, the Design Day Operations by service category, as obtained from Table 3.3-1 of the Addendum are used and assigned to the assumed typical aircraft for each service category. These typical aircraft are shown in Table 3. Two seating configurations (also shown in Table 3) are used to calculate total design day seats. First are the typical seating sizes as declared by the

manufacturers for the assumed aircraft types (shown later in Table 8), and second are the typical seats for the aircraft group as assumed by the Master Plan and can be found in the LAX Draft Master Plan Table IV-4.7.

Table 3. Assumed Aircraft Types, Seats and Load Factors.

Operation Type	Aircraft Type	Manufacturer Seats Assumed	"Typical" Seats Assumed in Master Plan	Load Factors*
Air Carrier	Boeing 757	200	185	0.6981
Commuter	Commuter	50	40.25 ¹	0.5675
Hawaii	Boeing 757	200	185	0.8988
International	MD 11	285	280	0.8076

* Load factors have been taken from the Draft LAX Master Plan, Table IV-2.8, LAX Draft Master Plan: Design Day forecasted load factors for year 2015.

¹Weighted average seats, for 12 class I and 20 class II commuter aircraft.

The seats are multiplied by load factors as assumed for each service category in the LAX Draft Master Plan. These numbers are also shown in Table 5 here. The Design Day Passengers are then obtained by multiplying number of operations by number of seats and the load factors. The Annual Passengers are obtained by multiplying the Design Day Passengers by the Annual Conversion Factor of 300.

The results of this analysis, using the Addendum's annual conversion factor of 300 are shown in Tables 4 and 5. Table 4, with the Addendum's assumed aircraft sizes and the annual conversion of 300 represents the passenger flows that result from the unmodified Addendum assumptions.

Table 4. Design Day & Annual Passengers, "Typical Seats" Assumed in Master Plan

Alternative	No Action/No Project	Alternative C	Alternative D
Design Day Operations Split*	1069 AC, 467 C, 54 H, 468 I	1120 AC, 317 C, 57H, 564 I	975 AC, 532 C, 53 H, 498 I
Design Day Passengers	263633	288969	259609
Annual Passengers	79089960	86690608	77882808
Design Day Passengers/NBEG	1400.81	1300.49	1451.14
Design Day Operations per NBEG	10.94	9.26	11.50

* AC: Air Carrier, C: Commuter, H: Hawaii, I: International operations.

Next in Table 5 we see the effect of adjusting aircraft seating capacities by using manufacturer specified figures for the aircraft categories assumed for each service type. The annual passenger flows are now higher. Such higher numbers reflect the capacity of the gates in the various categories, while the low numbers in Table 4 represent flows based on market assumptions of what airlines are assumed to use. In both cases these tables do not represent annual capacity since they are based on the Addendum's assumed conversion factor between design day and annual of 300, which is incorrect.

Table 5. Design Day Passengers, Manufacturer Seats Assumed

Alternative	No Action/No Project	Alternative C	Alternative D
Design Day Operations Split*	1069 AC, 467 C, 54 H, 468 I	1120 AC, 317 C, 57 H, 564 I	975 AC, 532 C, 53 H, 498 I
Design Day Passengers	279930	306262	275375
Annual Passengers	83978890	91878697	82612484
Design Day Passengers/NBEG	1487.41	1378.32	1539.27
Design Day Operations Per NBEG	10.94	9.26	11.50

* AC: Air Carrier, C: Commuter, H: Hawaii, I: International operations.

The figures shown in Table 4, completely reflecting the unmodified Master Plan assumptions corroborate the Addendum's estimation of the flow rates for the various alternatives. Under these assumptions all three alternatives C, D, and NA/NP have the same number of Design Day Operations, 2058, but as seen in Tables 4 and 5 these alternatives differ in the operations split. In the Alternative D projections, we can see that air carrier operations are significantly lower compared to Alternative C and to the NA/NP alternative assumptions. We can also see that the number of commuter operations is assumed to be the highest in Alternative D.

A Note on Addendum Assumptions of Operations By Service Type: These traffic assumptions seem to contradict the Master Plan's own market assumptions as stated in the Addendum (3.3.3 Air Service Changes) namely:

- *"Commuter operations would likely be reduced from 1996 levels, consistent with the forecasts for No Action/No Project and Alternative C, in order to maximize the number of passengers that could be served with a limited number of operations. It is also projected that some of the forecast commuter O&D demand would be served by domestic air carrier flights.*
- *Domestic air carrier connecting passengers would decrease from 2015 forecast levels to reflect the projected loss of connecting passengers from commuter flights."*

According to these assumptions, one would assume the number of commuter operations not to be as high as it is projected in Alternative D. So while all three alternatives are projected to have a drop in commuter operations from the 1996 level of 644 during the design day, Alternative D seems to have dropped the least. Instead we see the Design Day air carrier operations dropping measurably from 1096 in NA/NP and 1120 in Alternative C. to 975 in Alternative D.

Before subjecting the numbers obtained in tables 4 and 5 to sensitivity analysis a more detailed analysis of Design Day flows is conducted using the Master Plan Addendum's projected hourly operations by aircraft type. Given the importance of fleet mix and aircraft size assumptions, a detailed look at the assumed flights, aircraft type by aircraft type is more accurate than the numbers assumed on the basis of service category.

3.2 DETAILED PASSENGER CAPACITY AND SENSITIVITY ANALYSIS

Passenger capacity analysis involves calculation of passenger flow following the Master Plan assumptions of the fleet mix. The Design Day aircraft fleet mix was obtained from Table F-9 in the LAX Master Plan Addendum. This fleet mix contains all the flights in the Design Day: commercial, cargo, GA and military. In order to obtain the fleet mix for commercial passenger operations, cargo, general aviation and military flights are taken out according to the forecast in Tables IV-2.4 and IV-2.5 of the Draft LAX Master Plan. In the Draft Master Plan forecasted cargo, and GA operations are higher than the ones for Alternative D (i.e. 157 compared to 117 for cargo). Therefore, to obtain the cargo fleet mix for the Alternative D a pro-rated reduction of total operations is made using the percentage of each aircraft type in the projected cargo and GA fleets. The numbers are also adjusted to retain the projected distribution among service categories in the commercial operations flow³. These numbers are shown in Table 6.

Table 6. Cargo Fleet Mix.

Aircraft Type	Number of Forecasted Operations	Percentage of Operations	Percentage* Total Operations	Rounded Operations	Operations Alternative D	Percentage of Operations
B747-400	18	0.1146	13.41	13	13	0.1111
B747-100/200	18	0.1146	13.41	13	13	0.1111
MD11	15	0.0955	11.18	11	10	0.0854
DC10	16	0.1019	11.92	12	12	0.1025
A300	9	0.0573	6.71	7	6	0.0513
B767	15	0.0955	11.18	11	11	0.0940
B757	12	0.0764	8.94	9	8	0.0684
A310	10	0.0637	7.45	7	7	0.0598
B737	20	0.1274	14.90	15	15	0.1282
BE1	6	0.0382	4.47	4	6	0.0513
Small TP	18	0.1146	13.41	13	16	0.1367
Total	157			115	117	

The GA and military operations are shown in Table 7. By taking these out of the total in Table F-9, we obtain the Design Day fleet mix for passenger operations.

Table 7. GA and Military Fleet Mix.

Aircraft Type	MP Forecasted Operations	Alternative D Operations
Turboprop	81	76
Jet	29	28
Total	110	104

³ Operations by aircraft type in Alt. D are chosen to be lower than if we round the numbers we have from column 4. The reason is that simply rounding the numbers, will leave too many operations with larger aircraft (B737 to B747-400), thereby distorting the Addendum's assumed operations by commuter.

Having obtained the hourly Design Day commercial operations by aircraft type the next step is to perform a sensitivity analysis on aircraft seating capacities. For this sensitivity analysis two different seating analyses are made. In the first analysis, resulting in *Lower Range Seats* we use lower end of seats as shown in Table IV-2.3 (3 of 3) of LAX Draft Master Plan. The second analysis, resulting in *Higher Range Seats*, takes into account the number of seats for each aircraft type based on a combination of three sources:

1. Aircraft manufacturer specification.
2. Current fleet seating by the major US carriers serving LAX. (Obtained from major airlines' websites.)
3. Aircraft orders and options by the major US Carriers (As obtained from *Aviation Week and Space Technology 2003 Aerospace Source Book seating (Order/Options column)*)

Conservatively, we use the mid-range values rather than the high ends of the ranges shown from each source. All these numbers, the Master Plan's range, the manufacturer's range as well as the numbers used in the sensitivity analysis are shown in Table 8.

For each seating case the number of operations of each aircraft type, as projected in the Master Plan Addendum, is multiplied by its seats yielding the number of the Design Day seats. Table 9 shows the number of Design Day Offered Seats for Lower and Higher seat ranges respectively. The total Design Day Seats are shown in bold letters at the bottom of each table.

Table 8. Aircraft Type Seating Assumptions
Manufacturer's Seating Range, Master Plan Assumptions and Range Used in this Analysis

Having the number of the Design Day Seats for both seating ranges, a sensitivity analysis is next conducted on Annual Passengers, using different load factors and Annual Conversion Factors. The load factor of **0.7346** is the forecasted total commercial load factor, as obtained from Table IV-2.8 of the Draft Master Plan. Annual Passenger sensitivity analysis is presented in Tables 10 and 11, for lower and higher seat ranges, along with the design day passengers and design day passengers per operation. Bolded numbers are those exceeding 78.5 MAP.

Figures 1 and 2 show the numbers presented in Tables 10 and 11 in graphical form. Values that exceed 78.5 MAP are shown in gray, and the ones under are shown in white, thus making it easier to see influence of each assumption (load factor and annual conversion factor).

Figure 1. MAP Sensitivity Analysis, Lower Seat Range

Figure 2. MAP Sensitivity Analysis, Higher Seat Range

3.3 Capacity of Alternative D

To conclude regarding the capacity of the 153 gates as configured in Alternative D into 178.9 NBEG's we adopt the Master Plan's assumed average load factors of 73.46%. We also adopt LAX's prevailing Annual Conversion Factor of 310, and conservatively do not increase is to reflect possible spreading of the peak as traffic grows in face of capacity constraints. We also adopt the higher range seating of aircraft as described in the previous section as a better representation of the capacity of the gate positions, noting that it too is conservatively kept within the range of possible seating configurations rather than its top values. With that the capacity is estimated to be 87.24 MAP, as shown by the italicized number in Table 11.

3.4 Capacity Analysis for a Range of Gate Positions

The next step is to perform the capacity analysis for a range of gate positions in order to ascertain the number that would limit the capacity to 78 million. As shown in the results below, a significant reduction in gates or NBEG's would be needed to limit the capacity to 78 MAP. This question is addressed in this section.

To do this analysis, first the *Gate Passenger Flow Rate* is computed. This rate is the number of the Design Day Passengers divided by the number of NBEG's. Since it is the size as well as the number of gates that determines capacity, passenger flow per NBEG is used to calculate the capacity and then map it back on to the number of gates using the Master Plan Addendum's conversion assumptions, or gate mix. Table 12 shows Passenger Gate Flows for both Lower and Higher range seats and for each load factor used.

Table 12. Gate Passenger Flow: Design Day Passengers per NBEG

Load Factor	0.70	0.72	0.7346	0.74	0.76
Gate Passenger Flow-Lower Seat Range	1359	1398	1427	1437	1476
Gate Passenger Flow-Higher Seat Range	1499	1542	1574	1585	1628

We assume that Gate Passenger Flow is NBEG capacity in each load factor case. We also assume that the gate mix will not change. Right now the ratio between the nominal gates and NBEG's is 1.169. Sensitivity analysis can now be used to determine the change in capacity as the number of gates varies. Design Day Passengers are obtained by multiplying the average flow figures in Table 12 with the number of NBEG's. Annual capacity is then obtained by applying the conversion factor. The following tables (13-22) and figures (3-12) show the Annual Passengers served, for each load factor and number of NBEG's. We also show the number of nominal gates involved, following Alternative D ratio between nominal gates and NBEG's. As shown in Table 18 the figure of 87.24 MAP appears again as the capacity estimate.

3.5 Gate Capacity Analysis

The previous analysis showed the capacity of the current plan to be about 87 MAP. It also showed the relation between capacity and the number of gates or NBEG's, while maintaining the gate mix as it is presently proposed in Alternative D, and hence the same ratio between gates and NBEG's. In this section we calculate the capacity on the basis of the mix of gates proposed in Alternative D using the parameters defined in the Addendum for each gate design group. This permits the evaluation of the impact on capacity of reduction in gates of different size groups rather than simply number of gates and NBEG's as would be obtained from the previous section.

The gate mix proposed in the Addendum is found in Table E-2 of the Addendum. From the Table E-2 we see the gate mix and the gate assignment to airline operators. This information is used in the analysis, which is described in the following text.

Table 23 shows the range of load factors used in the sensitivity analysis. Bold-faced load factors are the Master Plan forecasted load factors for the 2015 Design Day, which can be found in the Table IV-2.8, LAX Draft Master Plan. Only the first row of bold face load factors has different values for different operations. The other bold-faced load factors are the LAX Master Plan's average load factors for all operation types. Hawaiian operations are not separated from the Air Carrier Operations, since from the Table E-2 and the airline definitions it was not possible to discern which gates would be used for Hawaiian operations.

Table 23. Range of Load Factors Used

Air Carrier	Commuter	International
0.7000	0.7000	0.7000
0.7100	0.7100	0.7100
0.6981*	0.5675*	0.8076*
0.7200	0.7200	0.7200
0.7346	0.7346	0.7346
0.7400	0.7400	0.7400

* The Master Plan's load factors by carrier group

The number of Design Day Operations for each gate design group is obtained by dividing the number of operations in each group by the number of gates in that group. The aircraft are grouped by gate size according to the Addendum's Table IV-4.7, and the number of gates in each design (or size) group is taken from the Addendum's Table E-2. The Design Day number of Operations for each gate size group is obtained from the Design Day fleet mix as shown in Table 9. The aircraft types are grouped according to the wing span range for each Aircraft Wing Span Group. The results are shown in Table 24. As before, the Design Day Passengers are calculated by multiplying for each gate in the gate size group the typical seats for that group by the corresponding load factor, and then multiplying that number by Design Day Operations per Gate.

Table 24. Operations per Gate for Proposed Gate Sizes and Fleet Mix

Gate Size	Aircraft Wing Span Group	Typical Seats	Number of Gates	Number of Operations	Design Day Operations per Gate
74X	VI	600	6	27	4.50
747	V	400	22	243	11.05
MD11, DC10, 767	IV	280	30	369	12.30
757	IIIa	185	23	386	16.78
MD80, 737	III	145	40	501	12.53
Commuter	I-III	40*	32	532	16.63

* Weighted average of typical seats for commuter I and II gates.

By considering the load factors discussed in the Master Plan we convert these operations into Design Day passenger flows, as shown in Table 25. The table shows the flows in passengers per NBEG as well, in order to facilitate sensitivity analysis.

Table 25. Design Day Passengers and Gate Passenger Flow.

Load Factors	Design Day Passengers	Passengers per NBEG

0.72	275241	1538.52
0.7346	280823	1569.72
0.74	282887	1581.26

The Master Plan's load factors by carrier group

Table 26 shows the sensitivity analysis of load factor and NBEG number changes, with the Annual Conversion Factor of 300. Table 27 shows the same sensitivity analysis for the Annual Conversion Factor of 310. In both tables besides the NBEG number we show the number of physical gates. The number of nominal gates is calculated assuming that the current Alternative D gate mix. By using the data in Tables 24 and 25 it is possible to study the effect of gate reductions in various mixes of gate design groups on capacity.

The results shown in Table 27 suggest that if the gate, or fleet group mix is not altered, and if the Master Plan's Design Day load factors are used then a reduction of about 10 gates would be necessary to limit the capacity to the 78.9 MAP. Different, higher or lower degrees of reduction can be also used if these reductions are articulated by specific design groups. Clearly a reduction by one NLA group VI gate would reduce the capacity considerably more than a reduction by one commuter Class I or II gate.

4. GENERAL CONCLUSIONS

We conclude that the capacity of the gate position system proposed in Alternative D and described in the Addendum: the 153 gates, or 178.9 NBEG's, will have a capacity conservatively estimated at 87 MAP. This capacity analysis is performed on the basis of most of the planning and forecast assumptions made in the Addendum. It is a conservative estimate because it does not allow for possible spreading of the peaks either daily or seasonally. The analysis uses the Master Plan's assumed hourly traffic patterns. It uses LAX's current seasonal traffic patterns. Adjusting either of these assumptions to reflect any possible de-peaking would result in a higher capacity estimate. The analysis uses the same aircraft fleet mix and gate size mix proposed in the Master Plan Addendum. However, it uses higher aircraft seating capacities that are considered more realistic and reflective of the capacity of the system. The Master Plan Addendum's figures appear to be based on market considerations rather than on the actual capacity possibilities.

A number of strategies are possible to limit the capacity to about 78 MAP as is the intended aim of Alternative D. All of these would entail a reduction in the number of gates provided. The actual number of gates to be reduced depends on how they are allocated among the different design groups. The analysis provided in this report permits exploring alternative ways of accomplishing the goal of limiting the capacity to about 78 MAP.

Adib Kanafani
Edward G. and John R. Cahill Professor of Civil Engineering
Department of Civil & Environmental Engineering
University of California at Berkeley
Telephone: 510- 642-0367; Fax: 510- 642-1246
E-mail: kanafani@ce.berkeley.edu; www.ce.berkeley.edu/~kanafani/

Adib Kanafani has been professor in the Civil and Environmental Engineering Department at the University of California at Berkeley since 1970. During this period he has taught and conducted research on air transportation, airport planning and design, and transportation systems, demand analysis and transportation economics. He was Director of Berkeley's Institute of Transportation Studies from 1983 to 1998 and Chairman of Berkeley's Department of Civil and Environmental Engineering from 1998 to 2002. He is a member of the National Academy of Engineering.

Kanafani's made contributions to air transportation including demand analysis, airport capacity analysis methods, and airline network analysis. He was a member of the research team that developed airport capacity analysis methods that are in widespread application in airport planning and design. He has also consulted extensively on airport planning and design for a number of agencies worldwide. In 1997 he was founding Co-Director of the National Center of Excellence in Aviation Operations Research, NEXTOR, a University/Industry partnership funded by the Federal Aviation Administration and headquartered at Berkeley.

Kanafani has had a long and distinguished public service record. He has served on a number of national and international advisory panels to Government and industry dealing a variety of aviation topics. He was a member of the FAA-Industry Task Force on Airport Capacity and Delay. He was also a member of a number of national Research Council study panels and committees including the Special Committee on Airport Landside Capacity, the Committee on Long-Term Airport Capacity Needs, and the Committee on Air Passenger Service and Safety Since Deregulation. He served the American Society of Civil Engineers as Chairman of the Air Transport Division, and the Transportation Research board, TRB as a member of the Special Committee on Air Transport Activities that helped usher air transportation into the scope of that organization, and where he is currently a member of the Executive Committee.

World Airports*

Capital Improvement Program

Fiscal Years 2001 to 2003

Runway Joint Reseal**Total Project Cost: \$2,200,000**

This project will reseal deteriorated joints on all runways at LAX. It is expected to be completed in Fiscal Year 2001.

<u>Fiscal Year</u>	<u>Future Bonds</u>	<u>Total</u>
2000-2001	\$2,200,000	\$2,200,000
2001-2002		
2002-2003		
Project Total		\$2,200,000

Miscellaneous Major Maintenance Projects**Total Project Cost: \$8,500,000**

These funds will cover various programmed miscellaneous Major Maintenance projects.

<u>Fiscal Year</u>	<u>Future Bonds</u>	<u>Revenue</u>	<u>Total</u>
2000-2001		\$2,000,000	\$2,000,000
2001-2002		\$3,500,000	\$3,500,000
2002-2003	\$3,000,000		\$3,000,000
Project Total			\$8,500,000

General**Century Cargo Complex**

This project has several elements, as follows:

 Cargo Building A**Total Project Cost: \$17,300,000**

This project will provide for the replacement of a 145,000-square-foot cargo building in the Century Cargo Complex. Construction began in September 1999 and is scheduled to be completed by September 2000.

<u>Fiscal Year</u>	<u>Revenue</u>	<u>Total</u>
Previous year(s)	\$8,000,000	\$8,000,000
2000-2001	\$9,300,000	\$9,300,000
2001-2002		
2002-2003		
Project Total		\$17,300,000

 Cargo Building A - Elevated Transfer Vehicle System**Total Project Cost: \$5,000,000**

This project will construct an Elevated Transfer Vehicle (ETV) system in Cargo Building A. The purpose of this system is to facilitate the transportation of cargo from the aircraft to the cargo facility. A consultant has been hired to determine whether or not this system is feasible in this facility.

<u>Fiscal Year</u>	<u>Revenue</u>	<u>Total</u>
2000-2001	\$5,000,000	\$5,000,000
2001-2002		
2002-2003		
Project Total		\$5,000,000

Avion Drive Realignment

Total Project Cost: \$23,000,000

This project will realign Avion Drive along Century Blvd. and Aviation Blvd. and will provide complete utility and drainage systems. Construction will begin in October 2000 with completion expected in September 2001.

<u>Fiscal Year</u>	<u>Future Bonds</u>	<u>Revenue</u>	<u>Total</u>
Previous year(s)		\$1,000,000	\$1,000,000
2000-2001	\$20,000,000		\$20,000,000
2001-2002	\$2,000,000		\$2,000,000
2002-2003			
Project Total			\$23,000,000

Air Freight Building 1 Remodel

Total Project Cost: \$4,200,000

This project involves modifications to Air Freight Building 1, including demolishing the northerly portion and relocating a vehicular ramp to rooftop parking. Construction will begin in June 2000 with completion in January 2001.

<u>Fiscal Year</u>	<u>Revenue</u>	<u>Total</u>
2000-2001	\$3,500,000	\$3,500,000
2001-2002	\$700,000	\$700,000
2002-2003		
Project Total		\$4,200,000

Air Freight Building 3 & USAir Cargo Demolition

Total Project Cost: \$3,100,000

This project will include the demolition of approximately 120,000 square feet of warehouse/office space in the Century Cargo Complex. Construction is scheduled to begin in April 2001 with completion in August 2001.

<u>Fiscal Year</u>	<u>Revenue</u>	<u>Total</u>
2000-2001	\$1,600,000	\$1,600,000
2001-2002	\$1,500,000	\$1,500,000
2002-2003		
Project Total		\$3,100,000

Cargo Building B

Total Project Cost: \$21,800,000

This project will provide for the replacement of a 150,000-square-foot cargo building in the Century Cargo Complex. Construction is scheduled to begin September 2001 with completion by September 2002.

Artist's rendering of Cargo Building B.

(Cargo Building B financing)

<u>Fiscal Year</u>	<u>Revenue</u>	<u>Total</u>
2000-2001		
2001-2002	\$17,000,000	\$17,000,000
2002-2003	\$4,800,000	\$4,800,000
Project Total		\$21,800,000

Demolition of Air Freight Building 8 & TWA Cargo Buildings

Total Project Cost: \$3,600,000

This project will demolish approximately 140,000 square feet of warehouse/office space in the Century Cargo Complex. Construction is scheduled to begin in October 2002 with completion in March 2003.

<u>Fiscal Year</u>	<u>Revenue</u>	<u>Total</u>
2000-2001		
2001-2002	\$600,000	\$600,000
2002-2003	\$3,000,000	\$3,000,000
Project Total		\$3,600,000

LAX Enhancement Program (Gateway LAX)

This project, entitled "Gateway LAX", consists of the installation of internally illuminated pylons, LAX letter signs and new landscaping at and along the main entrances to LAX.

Artist's conception of Gateway LAX at night.

Construction on this project began in January 2000. Gateway LAX is being developed in two phases. Phase I will create a clear and visually stimulating entrance into LAX, enhancements to the central terminal area and second level roadway, and a new comprehensive signage program to improve the overall functioning of the airport. The first phase will be complete by fall of 2000.

Phase II, scheduled to be completed by the end of 2001, includes the installation of new second level canopies, new treatments for the pedestrian bridges, and enhancements to the parking structures (including lighting improvements). The main program elements of work have been divided into various projects, as follows:

Waterview Landscaping

Total Project Cost: \$850,000

This project consists of landscaping the area along the south side of Waterview and Napoleon Streets between Pershing Drive and Vista Del Mar. The project also includes the construction of new meandering sidewalks, an irrigation system and airport fencing. The purpose of this project is to enhance the aesthetic character of the airport's northern border by creating an attractive, pedestrian-friendly environment while maintaining the ocean view.

 **DETERMINATION (To be completed by Lead Agency)**

On the basis of this initial evaluation:

I find that the proposed project COULD NOT have a significant effect on the environment, and a NEGATIVE DECLARATION will be prepared.

I find that although the proposed project could have a significant effect on the environment, there will not be a significant effect in this case because revisions on the project have been made by or agreed to by the project proponent. A MITIGATED NEGATIVE DECLARATION will be prepared.

I find the proposed project MAY have a significant effect on the environment, and an ENVIRONMENTAL IMPACT REPORT is required.

I find the proposed project MAY have a "potentially significant impact" or "potentially significant unless mitigated" impact on the environment, but at least one effect 1) has been adequately analyzed in an earlier document pursuant to applicable legal standards, and 2) has been addressed by mitigation measures based on earlier analysis as described on attached sheets. An ENVIRONMENTAL IMPACT REPORT is required, but it must analyze only the effects that remain to be addressed.

I find that although the proposed project could have a significant effect on the environment, because all potentially significant effects (a) have been analyzed adequately in an earlier EIR or NEGATIVE DECLARATION pursuant to applicable standards, and (b) have been avoided or mitigated pursuant to that earlier EIR or NEGATIVE DECLARATION, including revisions or mitigation measures that are imposed upon the proposed project, nothing further is required.

SIGNATURE

City Planner

TITLE

EVALUATION OF ENVIRONMENTAL IMPACTS:

- 1) A brief explanation is required for all answers except "No Impact" answers that are adequately supported by the information sources a lead agency cites in the parentheses following each question. A "No Impact" answer is adequately supported if the referenced information sources show that the impact simply does not apply to projects like the one involved (e.g., the project falls outside a fault rupture zone). A "No Impact" answer should be explained where it is based on project-specific factors as well as general standards (e.g., the project will not expose sensitive receptors to pollutants based on a project-specific screening analysis).
- 2) All answers must take account of the whole action involved, including off-site as well as on-site, cumulative as well as project-level, indirect as well as direct, and construction as well as operational impacts.
- 3) Once the lead agency has determined that a particular physical impact may occur, then the checklist answers must indicate whether the impact is potentially significant, less than significant with mitigation, or less than significant. "Potentially Significant Impact" is appropriate if there is substantial evidence that an effect may be significant. If there are one or more "Potentially Significant Impact" entries when the determination is made, an EIR is required.
- 4) "Negative Declaration: Less Than Significant With Mitigation Incorporated" applies where the incorporation of a mitigation measure has reduced an effect from "Potentially Significant Impact" to "Less Than Significant Impact." The lead agency must describe the mitigation measures, and briefly explain how they reduce the effect to a less than significant level (mitigation measures from Section

XVII, "Earlier Analysis," cross referenced).

- 5) Earlier analysis must be used where, pursuant to the tiering, program EIR, or other CEQA process, an effect has been adequately analyzed in an earlier EIR, or negative declaration. Section 15063 (c)(3)(D). In this case, a brief discussion should identify the following:
- 1) Earlier Analysis Used. Identify and state where they are available for review.
 - 2) Impacts Adequately Addressed. Identify which effects from the above checklist were within the scope of and adequately analyzed in an earlier document pursuant to applicable legal standards, and state whether such effects were addressed by mitigation measures based on the earlier analysis.
 - 3) Mitigation Measures. For effects that are "Less Than Significant With Mitigation Measures Incorporated," describe the mitigation measures which were incorporated or refined from the earlier document and the extent to which they address site-specific conditions for the project.
- 6) Lead agencies are encouraged to incorporate into the checklist references to information sources for potential impacts (e.g., general plans, zoning ordinances). Reference to a previously prepared or outside document should, where appropriate, include a reference to the page or pages where the statement is substantiated
- 7) Supporting Information Sources: A sources list should be attached, and other sources used or individuals contacted should be cited in the discussion.
- 8) This is only a suggested form, and lead agencies are free to use different formats; however, lead agencies should normally address the questions from this checklist that are relevant to a project's environmental effects in whichever format is selected.
- 9) The explanation of each issue should identify:
- 1) The significance criteria or threshold, if any, used to evaluate each question; and
 - 2) The mitigation measure identified, if any, to reduce the impact to less than significance.

ENVIRONMENTAL FACTORS POTENTIALLY AFFECTED:

The environmental factors checked below would be potentially affected by this project, involving at least one impact that is a "Potentially Significant Impact" as indicated by the checklist on the following pages.

INITIAL STUDY CHECKLIST (To be completed by the Lead City Agency)

 **BACKGROUND**

PROPONENT NAME	PHONE NUMBER
Mercury Air Group	

PROPONENT ADDRESS
7000 World Way Drive, Los Angeles, California

AGENCY REQUIRING CHECKLIST	DATE SUBMITTED
Los Angeles World Airports	April 17, 2003

PROPOSAL NAME (If Applicable)

 ENVIRONMENTAL IMPACTS

(Explanations of all potentially and less than significant impacts are required to be attached on separate sheets)

Potentially Significant Impact	Potentially Significant Unless Mitigation Incorporated	Less Than Significant Impact	No Impact
-----------------------------------	---	---------------------------------	-----------

I. AESTHETICS. Would the project:

- | | | | | |
|---|--------------------------|--------------------------|-------------------------------------|-------------------------------------|
| a. Have a substantial adverse effect on a scenic vista? | <input type="checkbox"/> | <input type="checkbox"/> | <input type="checkbox"/> | <input checked="" type="checkbox"/> |
| b. Substantially damage scenic resources, including, but not limited to, trees, rock outcroppings, and historic buildings, or other locally recognized desirable aesthetic natural feature within a city-designated scenic highway? | <input type="checkbox"/> | <input type="checkbox"/> | <input type="checkbox"/> | <input checked="" type="checkbox"/> |
| c. Substantially degrade the existing visual character or quality of the site and its surroundings? | <input type="checkbox"/> | <input type="checkbox"/> | <input type="checkbox"/> | <input checked="" type="checkbox"/> |
| d. Create a new source of substantial light or glare which would adversely affect day or nighttime views in the area? | <input type="checkbox"/> | <input type="checkbox"/> | <input checked="" type="checkbox"/> | <input type="checkbox"/> |

II. AGRICULTURAL RESOURCES. In determining whether impacts to agricultural resources are significant environmental effects, lead agencies may refer to the California Agricultural Land Evaluation and Site Assessment Model (1997) prepared by the California Department of Conservation as an optional model to use in assessing impacts on agriculture and farmland. Would the project:

- | | | | | |
|---|--------------------------|--------------------------|--------------------------|-------------------------------------|
| a. Convert Prime Farmland, Unique Farmland, or Farmland of Statewide Importance, as shown on the maps prepared pursuant to the Farmland Mapping and Monitoring Program of the California Resources Agency, to non-agricultural use? | <input type="checkbox"/> | <input type="checkbox"/> | <input type="checkbox"/> | <input checked="" type="checkbox"/> |
| b. Conflict the existing zoning for agricultural use, or a Williamson Act Contract? | <input type="checkbox"/> | <input type="checkbox"/> | <input type="checkbox"/> | <input checked="" type="checkbox"/> |
| c. Involve other changes in the existing environment which, due to their location or nature, could result in conversion of Farmland, to non-agricultural use? | <input type="checkbox"/> | <input type="checkbox"/> | <input type="checkbox"/> | <input checked="" type="checkbox"/> |

III. AIR QUALITY. The significance criteria established by the South Coast Air Quality Management District (SCAQMD) may be relied upon to make the following determinations. Would the project result in:

- | | | | | |
|--|--------------------------|--------------------------|-------------------------------------|-------------------------------------|
| a. Conflict with or obstruct implementation of the SCAQMD or Congestion Management Plan? | <input type="checkbox"/> | <input type="checkbox"/> | <input type="checkbox"/> | <input checked="" type="checkbox"/> |
| b. Violate any air quality standard or contribute substantially to an existing or projected air quality violation? | <input type="checkbox"/> | <input type="checkbox"/> | <input checked="" type="checkbox"/> | <input type="checkbox"/> |
| c. Result in a cumulatively considerable net increase of any criteria pollutant for which the air basin is non-attainment (ozone, carbon monoxide, & PM ₁₀) under an applicable federal or state ambient air quality standard? | <input type="checkbox"/> | <input type="checkbox"/> | <input checked="" type="checkbox"/> | <input type="checkbox"/> |
| d. Expose sensitive receptors to substantial pollutant concentrations? | <input type="checkbox"/> | <input type="checkbox"/> | <input type="checkbox"/> | <input checked="" type="checkbox"/> |

	Potentially Significant Impact	Potentially Significant Unless Mitigation Incorporated	Less Than Significant Impact	No Impact
--	--------------------------------	--	------------------------------	-----------

e. Create objectionable odors affecting a substantial number of people?

<input type="checkbox"/>	<input type="checkbox"/>	<input type="checkbox"/>	<input checked="" type="checkbox"/>
--------------------------	--------------------------	--------------------------	-------------------------------------

IV. BIOLOGICAL RESOURCES. Would the project:

a. Have a substantial adverse effect, either directly or through habitat modification, on any species identified as a candidate, sensitive, or special status species in local or regional plans, policies, or regulations by the California Department of Fish and Game or U.S. Fish and Wildlife Service ?

<input type="checkbox"/>	<input type="checkbox"/>	<input type="checkbox"/>	<input checked="" type="checkbox"/>
--------------------------	--------------------------	--------------------------	-------------------------------------

b. Have a substantial adverse effect on any riparian habitat or other sensitive natural community identified in the City or regional plans, policies, regulations by the California Department of Fish and Game or U.S. Fish and Wildlife Service ?

<input type="checkbox"/>	<input type="checkbox"/>	<input type="checkbox"/>	<input checked="" type="checkbox"/>
--------------------------	--------------------------	--------------------------	-------------------------------------

c. Have a substantial adverse effect on federally protected wetlands as defined by Section 404 of the Clean Water Act (including, but not limited to, marsh vernal pool, coastal, etc.) Through direct removal, filling, hydrological interruption, or other means?

<input type="checkbox"/>	<input type="checkbox"/>	<input type="checkbox"/>	<input checked="" type="checkbox"/>
--------------------------	--------------------------	--------------------------	-------------------------------------

d. Interfere substantially with the movement of any native resident or migratory fish or wildlife species or with established native resident or migratory wildlife corridors, or impede the use of native wildlife nursery sites?

<input type="checkbox"/>	<input type="checkbox"/>	<input type="checkbox"/>	<input checked="" type="checkbox"/>
--------------------------	--------------------------	--------------------------	-------------------------------------

e. Conflict with any local policies or ordinances protecting biological resources, such as tree preservation policy or ordinance (e.g., oak trees or California walnut woodlands)?

<input type="checkbox"/>	<input type="checkbox"/>	<input type="checkbox"/>	<input checked="" type="checkbox"/>
--------------------------	--------------------------	--------------------------	-------------------------------------

f. Conflict with the provisions of an adopted Habitat Conservation Plan, Natural Community Conservation Plan, or other approved local, regional, or state habitat conservation plan?

<input type="checkbox"/>	<input type="checkbox"/>	<input type="checkbox"/>	<input checked="" type="checkbox"/>
--------------------------	--------------------------	--------------------------	-------------------------------------

V. CULTURAL RESOURCES: Would the project:

a. Cause a substantial adverse change in significance of a historical resource as defined in State CEQA §15064.5?

<input type="checkbox"/>	<input type="checkbox"/>	<input type="checkbox"/>	<input checked="" type="checkbox"/>
--------------------------	--------------------------	--------------------------	-------------------------------------

b. Cause a substantial adverse change in significance of an archaeological resource pursuant to State CEQA §15064.5?

<input type="checkbox"/>	<input type="checkbox"/>	<input type="checkbox"/>	<input checked="" type="checkbox"/>
--------------------------	--------------------------	--------------------------	-------------------------------------

c. Directly or indirectly destroy a unique paleontological resource or site or unique geologic feature?

<input type="checkbox"/>	<input type="checkbox"/>	<input type="checkbox"/>	<input checked="" type="checkbox"/>
--------------------------	--------------------------	--------------------------	-------------------------------------

d. Disturb any human remains, including those interred outside of formal cemeteries?

<input type="checkbox"/>	<input type="checkbox"/>	<input type="checkbox"/>	<input checked="" type="checkbox"/>
--------------------------	--------------------------	--------------------------	-------------------------------------

VI. GEOLOGY AND SOILS. Would the project:

a. Exposure of people or structures to potential substantial adverse effects, including the risk of loss, injury or death involving :

<input type="checkbox"/>	<input type="checkbox"/>	<input checked="" type="checkbox"/>	<input type="checkbox"/>
--------------------------	--------------------------	-------------------------------------	--------------------------

	Potentially Significant Impact	Potentially Significant Unless Mitigation Incorporated	Less Than Significant Impact	No Impact
i. Rupture of a known earthquake fault, as delineated on the most recent Alquist-Priolo Earthquake Fault Zoning Map issued by the State Geologist for the area or based on other substantial evidence of a known fault? Refer to Division of Mines and Geology Special Publication 42.	<input type="checkbox"/>	<input type="checkbox"/>	<input checked="" type="checkbox"/>	<input type="checkbox"/>
ii. Strong seismic ground shaking?	<input type="checkbox"/>	<input type="checkbox"/>	<input checked="" type="checkbox"/>	<input type="checkbox"/>
iii. Seismic-related ground failure, including liquefaction?	<input type="checkbox"/>	<input type="checkbox"/>	<input type="checkbox"/>	<input checked="" type="checkbox"/>
iv. Landslides?	<input type="checkbox"/>	<input type="checkbox"/>	<input type="checkbox"/>	<input checked="" type="checkbox"/>
b. Result in substantial soil erosion or the loss of topsoil?	<input type="checkbox"/>	<input type="checkbox"/>	<input type="checkbox"/>	<input checked="" type="checkbox"/>
c. Be located on a geologic unit or soil that is unstable, or that would become unstable as a result of the project, and potential result in on- or off-site landslide, lateral spreading, subsidence, liquefaction, or collapse?	<input type="checkbox"/>	<input type="checkbox"/>	<input type="checkbox"/>	<input checked="" type="checkbox"/>
d. Be located on expansive soil, as defined in Table 18-1-B of the Uniform Building Code (1994), creating substantial risks to life or property?	<input type="checkbox"/>	<input type="checkbox"/>	<input type="checkbox"/>	<input checked="" type="checkbox"/>
e. Have soils incapable of adequately supporting the use of septic tanks or alternative waste water disposal systems where sewers are not available for the disposal of waste water?	<input type="checkbox"/>	<input type="checkbox"/>	<input type="checkbox"/>	<input checked="" type="checkbox"/>

VII. HAZARDS AND HAZARDOUS MATERIALS. Would the project:

a. Create a significant hazard to the public or the environment through the routine transport, use, or disposal of hazardous materials	<input type="checkbox"/>	<input type="checkbox"/>	<input checked="" type="checkbox"/>	<input type="checkbox"/>
b. Create a significant hazard to the public or the environment through reasonably foreseeable upset and accident conditions involving the release of hazardous materials into the environment?	<input type="checkbox"/>	<input type="checkbox"/>	<input checked="" type="checkbox"/>	<input type="checkbox"/>
c. Emit hazardous emissions or handle hazardous or acutely hazardous materials, substances, or waste within one-quarter mile of an existing or proposed school?	<input type="checkbox"/>	<input type="checkbox"/>	<input type="checkbox"/>	<input checked="" type="checkbox"/>
d. Be located on a site which is included on a list of hazardous materials sites compiled pursuant to Government Code Section 65962.5 and, as a result, would it create a significant hazard to the public or the environment?	<input type="checkbox"/>	<input type="checkbox"/>	<input type="checkbox"/>	<input checked="" type="checkbox"/>
e. For a project located within an airport land use plan or, where such a plan has not been adopted, within two miles of a public airport or public use airport, would the project result in a safety hazard for people residing or working in the project area?	<input type="checkbox"/>	<input type="checkbox"/>	<input checked="" type="checkbox"/>	<input type="checkbox"/>
f. For a project within the vicinity of a private airstrip, would the project result in a safety hazard for the people residing or working in the area?	<input type="checkbox"/>	<input type="checkbox"/>	<input type="checkbox"/>	<input checked="" type="checkbox"/>
g. Impair implementation of or physically interfere with an adopted emergency response plan or emergency evacuation plan?	<input type="checkbox"/>	<input type="checkbox"/>	<input type="checkbox"/>	<input checked="" type="checkbox"/>

	Potentially Significant Impact	Potentially Significant Unless Mitigation Incorporated	Less Than Significant Impact	No Impact
--	--------------------------------	--	------------------------------	-----------

h. Expose people or structures to a significant risk of loss, injury or death involving wildland fires, including where wildlands are adjacent to urbanized areas or where residences are intermixed with wildlands?

<input type="checkbox"/>	<input type="checkbox"/>	<input type="checkbox"/>	<input checked="" type="checkbox"/>
--------------------------	--------------------------	--------------------------	-------------------------------------

VIII. HYDROLOGY AND WATER QUALITY. Would the proposal result in:

a. Violate any water quality standards or waste discharge requirements?

<input type="checkbox"/>	<input type="checkbox"/>	<input type="checkbox"/>	<input checked="" type="checkbox"/>
--------------------------	--------------------------	--------------------------	-------------------------------------

b. Substantially deplete groundwater supplies or interfere with groundwater recharge such that there would be a net deficit in aquifer volume or a lowering of the local groundwater table level (e.g., the production rate of pre-existing nearby wells would drop to a level which would not support existing land uses or planned land uses for which permits have been granted)?

<input type="checkbox"/>	<input type="checkbox"/>	<input type="checkbox"/>	<input checked="" type="checkbox"/>
--------------------------	--------------------------	--------------------------	-------------------------------------

c. Substantially alter the existing drainage pattern of the site or area, including through the alteration of the course of a stream or river, in a manner which would result in substantial erosion or siltation on- or off-site?

<input type="checkbox"/>	<input type="checkbox"/>	<input type="checkbox"/>	<input checked="" type="checkbox"/>
--------------------------	--------------------------	--------------------------	-------------------------------------

d. Substantially alter the existing drainage pattern of the site or area, including through the alteration of the course of a stream or river, or substantially increase the rate or amount of surface runoff in a manner which would result in flooding on- or off site?

<input type="checkbox"/>	<input type="checkbox"/>	<input type="checkbox"/>	<input checked="" type="checkbox"/>
--------------------------	--------------------------	--------------------------	-------------------------------------

e. Create or contribute runoff water which would exceed the capacity of existing or planned stormwater drainage systems or provide substantial additional sources of polluted runoff?

<input type="checkbox"/>	<input type="checkbox"/>	<input type="checkbox"/>	<input checked="" type="checkbox"/>
--------------------------	--------------------------	--------------------------	-------------------------------------

f. Otherwise substantially degrade water quality?

<input type="checkbox"/>	<input type="checkbox"/>	<input type="checkbox"/>	<input checked="" type="checkbox"/>
--------------------------	--------------------------	--------------------------	-------------------------------------

g. Place housing within a 100-year flood plain as mapped on federal Flood Hazard Boundary or Flood Insurance Rate Map or other flood hazard delineation map?

<input type="checkbox"/>	<input type="checkbox"/>	<input type="checkbox"/>	<input checked="" type="checkbox"/>
--------------------------	--------------------------	--------------------------	-------------------------------------

h. Place within a 100-year flood plain structures which would impede or redirect flood flows?

<input type="checkbox"/>	<input type="checkbox"/>	<input type="checkbox"/>	<input checked="" type="checkbox"/>
--------------------------	--------------------------	--------------------------	-------------------------------------

i. Expose people or structures to a significant risk of loss, injury or death involving flooding, including flooding as a result of the failure of a levee or dam?

<input type="checkbox"/>	<input type="checkbox"/>	<input type="checkbox"/>	<input checked="" type="checkbox"/>
--------------------------	--------------------------	--------------------------	-------------------------------------

j. Inundation by seiche, tsunami, or mudflow?

<input type="checkbox"/>	<input type="checkbox"/>	<input type="checkbox"/>	<input checked="" type="checkbox"/>
--------------------------	--------------------------	--------------------------	-------------------------------------

IX. LAND USE AND PLANNING. Would the project:

a. Physically divide an established community?

<input type="checkbox"/>	<input type="checkbox"/>	<input type="checkbox"/>	<input checked="" type="checkbox"/>
--------------------------	--------------------------	--------------------------	-------------------------------------

b. Conflict with applicable land use plan, policy or regulation of an agency with jurisdiction over the project (including but not limited to the general plan, specific plan, coastal program, or zoning ordinance) adopted for the purpose of avoiding or mitigating an environmental effect?

<input type="checkbox"/>	<input type="checkbox"/>	<input type="checkbox"/>	<input checked="" type="checkbox"/>
--------------------------	--------------------------	--------------------------	-------------------------------------

	Potentially Significant Impact	Potentially Significant Unless Mitigation Incorporated	Less Than Significant Impact	No Impact
--	--------------------------------	--	------------------------------	-----------

c. Conflict with any applicable habitat conservation plan or natural community conservation plan?

<input type="checkbox"/>	<input type="checkbox"/>	<input type="checkbox"/>	<input checked="" type="checkbox"/>
--------------------------	--------------------------	--------------------------	-------------------------------------

X. MINERAL RESOURCES. Would the project:

a. Result in the loss of availability of a known mineral resource that would be of value to the region and the residents of the state?

<input type="checkbox"/>	<input type="checkbox"/>	<input type="checkbox"/>	<input checked="" type="checkbox"/>
--------------------------	--------------------------	--------------------------	-------------------------------------

b. Result in the loss of availability of a locally-important mineral resource recovery site delineated on a local general plan, specific plan, or other land use plan?

<input type="checkbox"/>	<input type="checkbox"/>	<input type="checkbox"/>	<input checked="" type="checkbox"/>
--------------------------	--------------------------	--------------------------	-------------------------------------

XI. NOISE. Would the project:

a. Exposure of persons to or generation of noise in level in excess of standards established in the local general plan or noise ordinance, or applicable standards of other agencies?

<input type="checkbox"/>	<input type="checkbox"/>	<input checked="" type="checkbox"/>	<input type="checkbox"/>
--------------------------	--------------------------	-------------------------------------	--------------------------

b. Exposure of people to or generation of excessive groundborne vibration or groundborne noise levels?

<input type="checkbox"/>	<input type="checkbox"/>	<input checked="" type="checkbox"/>	<input type="checkbox"/>
--------------------------	--------------------------	-------------------------------------	--------------------------

c. A substantial permanent increase in ambient noise levels in the project vicinity above levels existing without the project?

<input type="checkbox"/>	<input type="checkbox"/>	<input checked="" type="checkbox"/>	<input type="checkbox"/>
--------------------------	--------------------------	-------------------------------------	--------------------------

d. A substantial temporary or periodic increase in ambient noise levels in the project vicinity above levels existing without the project?

<input type="checkbox"/>	<input type="checkbox"/>	<input checked="" type="checkbox"/>	<input type="checkbox"/>
--------------------------	--------------------------	-------------------------------------	--------------------------

e. For a project located within an airport land use plan or, where such a plan has not been adopted, within two miles of a public airport or public use airport, would the project expose people residing or working in the project area to excessive noise levels?

<input type="checkbox"/>	<input type="checkbox"/>	<input type="checkbox"/>	<input checked="" type="checkbox"/>
--------------------------	--------------------------	--------------------------	-------------------------------------

f. For a project within the vicinity of a private airstrip, would the project expose people residing or working in the project area to excessive noise levels?

<input type="checkbox"/>	<input type="checkbox"/>	<input type="checkbox"/>	<input checked="" type="checkbox"/>
--------------------------	--------------------------	--------------------------	-------------------------------------

XII. POPULATION AND HOUSING. Would the project:

a. Induce substantial population growth in an area either directly (for example, by proposing new homes and businesses) or indirectly (for example, through extension of roads or other infrastructure)?

<input type="checkbox"/>	<input type="checkbox"/>	<input type="checkbox"/>	<input checked="" type="checkbox"/>
--------------------------	--------------------------	--------------------------	-------------------------------------

b. Displace substantial numbers of existing housing necessitating the construction of replacement housing elsewhere?

<input type="checkbox"/>	<input type="checkbox"/>	<input type="checkbox"/>	<input checked="" type="checkbox"/>
--------------------------	--------------------------	--------------------------	-------------------------------------

c. Displace substantial numbers of people necessitating the construction of replacement housing elsewhere?

<input type="checkbox"/>	<input type="checkbox"/>	<input type="checkbox"/>	<input checked="" type="checkbox"/>
--------------------------	--------------------------	--------------------------	-------------------------------------

Potentially Significant Impact	Potentially Significant Unless Mitigation Incorporated	Less Than Significant Impact	No Impact
-----------------------------------	---	---------------------------------	-----------

XIII. PUBLIC SERVICES. Would the project result in substantial adverse physical impacts associated with the provision of new or physically altered governmental facilities, construction of which could cause significant environmental impacts, in order to maintain acceptable service ratios, response times or other performance objectives for any of the public services:

- | | | | | |
|---|--------------------------|--------------------------|--------------------------|-------------------------------------|
| a. Fire protection? | <input type="checkbox"/> | <input type="checkbox"/> | <input type="checkbox"/> | <input checked="" type="checkbox"/> |
| b. Police protection? | <input type="checkbox"/> | <input type="checkbox"/> | <input type="checkbox"/> | <input checked="" type="checkbox"/> |
| c. Schools? | <input type="checkbox"/> | <input type="checkbox"/> | <input type="checkbox"/> | <input checked="" type="checkbox"/> |
| d. Parks? | <input type="checkbox"/> | <input type="checkbox"/> | <input type="checkbox"/> | <input checked="" type="checkbox"/> |
| e. Other governmental services (including roads)? | <input type="checkbox"/> | <input type="checkbox"/> | <input type="checkbox"/> | <input checked="" type="checkbox"/> |

XIV. RECREATION.

- | | | | | |
|--|--------------------------|--------------------------|--------------------------|-------------------------------------|
| a. Would the project increase the use of existing neighborhood and regional parks or other recreational facilities such that substantial physical deterioration of the facility would occur or be accelerated? | <input type="checkbox"/> | <input type="checkbox"/> | <input type="checkbox"/> | <input checked="" type="checkbox"/> |
| b. Does the project include recreational facilities or require the construction or expansion of recreational facilities which might have an adverse physical effect on the environment? | <input type="checkbox"/> | <input type="checkbox"/> | <input type="checkbox"/> | <input checked="" type="checkbox"/> |

XV. TRANSPORTATION/CIRCULATION. Would the project:

- | | | | | |
|--|--------------------------|--------------------------|--------------------------|-------------------------------------|
| a. Cause an increase in traffic which is substantial in relation to the existing traffic load and capacity of the street system (i.e., result in a substantial increase in either the number of vehicle trips, the volume to ratio capacity on roads, or congestion at intersections)? | <input type="checkbox"/> | <input type="checkbox"/> | <input type="checkbox"/> | <input checked="" type="checkbox"/> |
| b. Exceed, either individually or cumulatively, a level of service standard established by the county congestion management agency for designated roads or highways? | <input type="checkbox"/> | <input type="checkbox"/> | <input type="checkbox"/> | <input checked="" type="checkbox"/> |
| c. Result in a change in air traffic patterns, including either an increase in traffic levels or a change in location that results in substantial safety risks? | <input type="checkbox"/> | <input type="checkbox"/> | <input type="checkbox"/> | <input checked="" type="checkbox"/> |
| d. Substantially increase hazards to a design feature (e.g., sharp curves or dangerous intersections) or incompatible uses (e.g., farm equipment)? | <input type="checkbox"/> | <input type="checkbox"/> | <input type="checkbox"/> | <input checked="" type="checkbox"/> |
| e. Result in inadequate emergency access? | <input type="checkbox"/> | <input type="checkbox"/> | <input type="checkbox"/> | <input checked="" type="checkbox"/> |
| f. Result in inadequate parking capacity? | <input type="checkbox"/> | <input type="checkbox"/> | <input type="checkbox"/> | <input checked="" type="checkbox"/> |
| g. Conflict with adopted policies, plans, or programs supporting alternative transportation (e.g., bus turnouts, bicycle racks)? | <input type="checkbox"/> | <input type="checkbox"/> | <input type="checkbox"/> | <input checked="" type="checkbox"/> |

	Potentially Significant Impact	Potentially Significant Unless Mitigation Incorporated	Less Than Significant Impact	No Impact
--	--------------------------------	--	------------------------------	-----------

XVI. UTILITIES. Would the project:

- | | | | | |
|---|--------------------------|--------------------------|--------------------------|-------------------------------------|
| a. Exceed wastewater treatment requirements of the applicable Regional Water Quality Control Board? | <input type="checkbox"/> | <input type="checkbox"/> | <input type="checkbox"/> | <input checked="" type="checkbox"/> |
| b. Require or result in the construction of new water or wastewater treatment facilities or expansion of existing facilities, the construction of which could cause significant environmental effects? | <input type="checkbox"/> | <input type="checkbox"/> | <input type="checkbox"/> | <input checked="" type="checkbox"/> |
| c. Require or result in the construction of new stormwater drainage facilities or expansion of existing facilities, the construction of which could cause significant environmental effects? | <input type="checkbox"/> | <input type="checkbox"/> | <input type="checkbox"/> | <input checked="" type="checkbox"/> |
| d. Have sufficient water supplies available to serve the project from existing entitlements and resource, or are new or expanded entitlements needed? | <input type="checkbox"/> | <input type="checkbox"/> | <input type="checkbox"/> | <input checked="" type="checkbox"/> |
| e. Result in a determination by the wastewater treatment provider which serves or may serve the project that it has adequate capacity to serve the project's projected demand in addition to the provider's existing commitments? | <input type="checkbox"/> | <input type="checkbox"/> | <input type="checkbox"/> | <input checked="" type="checkbox"/> |
| f. Be served by a landfill with sufficient permitted capacity to accommodate the project's solid waste disposal needs? | <input type="checkbox"/> | <input type="checkbox"/> | <input type="checkbox"/> | <input checked="" type="checkbox"/> |
| g. Comply with federal, state, and local statutes and regulations related to solid waste? | <input type="checkbox"/> | <input type="checkbox"/> | <input type="checkbox"/> | <input checked="" type="checkbox"/> |

XVII. MANDATORY FINDINGS OF SIGNIFICANCE.

- | | | | | |
|--|--------------------------|--------------------------|-------------------------------------|-------------------------------------|
| a. Does the project have the potential to degrade the quality of the environment, substantially reduce the habitat of fish or wildlife species, cause a fish or wildlife population to drop below self-sustaining levels, threaten to eliminate a plant or animal community, reduce the number or restrict the range of a rare or endangered plant or animal or eliminate important examples of the major periods of California history or prehistory? | <input type="checkbox"/> | <input type="checkbox"/> | <input type="checkbox"/> | <input checked="" type="checkbox"/> |
| b. Does the project have impacts which are individually limited, but cumulatively considerable? ("Cumulatively considerable" means that the incremental effects of an individual project are considerable when viewed in connection with the effects of past projects, the effects of other current projects, and the effects of probable future projects). | <input type="checkbox"/> | <input type="checkbox"/> | <input checked="" type="checkbox"/> | <input type="checkbox"/> |
| c. Does the project have environmental effects which cause substantial adverse effects on human beings, either directly or indirectly? | <input type="checkbox"/> | <input type="checkbox"/> | <input type="checkbox"/> | <input checked="" type="checkbox"/> |

DISCUSSION OF THE ENVIRONMENTAL EVALUATION (Attach additional sheets if necessary)

(See Attachments A and B)

**ATTACHMENT A
PROJECT DESCRIPTION**

1.0 INTRODUCTION

The Applicant, Mercury Air Group, Inc. (MAG), proposes to relocate their existing Mercury Air Center Fixed Base Operation (FBO) at Los Angeles International Airport (LAX), 7000 World Way West, to another site on the airport located near the northwest corner of Sepulveda Boulevard and Imperial Highway. The proposed project would situate Mercury Air Center in a more accessible location within LAX as well as consolidate their existing FBO activities.

2.0 PROJECT LOCATION AND SURROUNDING USES

As shown in Figure 1 on page A-2, the project site is located within the City of Los Angeles on Los Angeles World Airports (LAWA) property. The jurisdictional boundary between the City of Los Angeles and the City of El Segundo is formed by Imperial Highway, which also defines the southern boundary of the airport. More specifically, the approximately 15-acre project site is located near the northwest corner of Sepulveda Boulevard and Imperial Highway (see Figure 2 on page A-3). Regional access is provided by the Century Freeway (Interstate 105), an east-west freeway, which is located south of the proposed project area and crosses the San Diego Freeway (Interstate 405), a north-south freeway located east of the project area. Major roadways serving the site include Imperial Highway, Century Boulevard and Manchester Avenue, which run in an east-west direction and Sepulveda Boulevard, Pershing Drive, and Vista Del Mar which run in a north-south direction.

Two buildings, the B-4 Hangar (approximately 67,200 square feet) and Air Freight Building 12 (approximately 15,000 square feet), currently occupy the approximately 15-acre project site (see Figure 3 on page A-4). The project site is surrounded by LAX property to the north and west, as well as to the east across Sepulveda Boulevard. Immediately to the north of the project site is the South Airfield Complex; immediately to the west are air cargo facilities and to the east across Sepulveda Boulevard is a Fixed Base Operation (FBO), run by Garrett Aviation Service. At the southwest corner of the project site on airport property is Federal Aviation Administration (FAA) Airport Surface Detection Equipment (ASDE-3). There are commercial uses located to the south across Imperial Boulevard in the City of El Segundo. There are also residential uses located in El Segundo further south from the airport behind the commercial uses and to the west along the south side of Imperial Highway.

3.0 STATEMENT OF PROJECT OBJECTIVES

Section 15124(b) of the CEQA Guidelines states that the Project Description shall contain “A statement of the objectives sought by the proposed project.” Section 15125(b) of the CEQA Guidelines further states that, “The statement of objectives should include the underlying purpose of the project.” The main purpose of this project is to alleviate severely constrained operating conditions at the present Mercury Air Center FBO by relocating and developing a significantly improved FBO at LAX that will provide the following:

- A building that will contribute to improved productivity of Mercury operations, management and customer service personnel. The new building will improve productivity through increased space, a more functional building plan compared to the current facility, improved visibility of and by management, and more harmonious and pleasing customer service areas;
- A building that contains space and flexibility for whatever new security requirements that may be imposed as a function of September 11, 2001;
- A larger aircraft parking area that will allow less stacking of aircraft and therefore safer and more productive work and faster service on the ramp area when receiving, parking and dispatching aircraft;
- An operational area that will consolidate various MAG employee parking areas and eliminate current use of the Imperial Terminal parking. This will contribute to productivity, security and reduced travel time for employees; and
- A new FBO access point that will eliminate the current security and safety issues resulting from the requirement to enter the American Airlines gate from World Way West and travel across airport operation areas in order to arrive at the current FBO. This will improve security, reduce trips across the operations area, increase airfield safety, and reduce vehicular travel time throughout the area; and
- Consolidation at LAX of the areas used by FBOs and associated segregation of General Aviation from airline operations resulting in enhanced safety.

4.0 DESCRIPTION OF THE PROPOSED PROJECT

The proposed project is the relocation and consolidation of the Mercury Air Center Fixed Base Operation (FBO)¹ that is currently located at Los Angeles International Airport (LAX) at 7000 World Way West. The proposed site is located at 6401 and 6411 West Imperial Highway. Figure 2 shows the current location of the Mercury Air Center FBO and the site proposed for its relocation.

LAX is approximately 3,640 acres in size. Ancillary uses, which include general aviation, ground service, airline administration and maintenance, LAWA and FAA offices, flight kitchens, and other airport related uses, occupy approximately 364 acres.² The current zoning on the airport property is primarily light industrial (M2) and heavy industrial (M3). The current and proposed sites are zoned M3-1.

Existing Mercury Air Center Facilities and Operations

Mercury's current site, which is leased from the airport, is 1.96 acres and includes a 2,000 square foot FBO facility with a kitchen, restrooms, a flight planning room, a reception area and offices. The current hours of operation for the FBO are from 6:00 A.M. to 11:00 P.M. The existing FBO site includes one acre of ramp parking, one airframe and power (A&P) facility, one line service facility, approximately 22 vehicle parking spaces, and space for 30 pieces of FBO ground services and A&P equipment. Mercury also leases, uses, and rents space at various locations on the airport in order to operate the FBO. Mercury leases 0.6 acres from American Airlines, of which approximately two-thirds is used for parking aircraft and one-third for air maintenance facility and vehicular parking. Between 7:00 A.M. and 7:00 P.M., Mercury also has daily use of 0.8 acres of American Airlines property adjacent to the 0.6 acres leased from American Airlines. When adequate aircraft parking space is not available at the Mercury FBO facility, Mercury rents individual parking spots (approximately one acre) from Continental Airlines for wide-body aircraft overflow parking. In addition, Mercury rents approximately 0.7 acres at Imperial Terminal to provide 90 vehicular parking spaces, 60 of which are used by fueling employees and 30 are used by air cargo employees. Mercury also rents approximately 0.5 acres from American Airlines for an additional 55 vehicular parking spaces, 19 of which are used by the FBO and 36 are used for aircraft maintenance staff. When combining the 1.96 acres FBO site with other areas leased, used, and rented by MAG, approximately 4.56 acres are currently used by MAG.

¹ A Fixed Based Operation (FBO) is a commercial operation that is authorized by agreement with an airport operator to provide to the public at a minimum the following activities at the airport: sale of aviation fuels and lubricants; ancillary aircraft ground services and support; tiedown, hangar, and parking; and aircraft maintenance.

² Draft EIR/EIS for the LAX Proposed Master Plan Improvements, January 2001.

Mercury's current FBO activities are severely constrained. With regard to aircraft parking spaces, unlike commercial airline operations that park a single aircraft at a specifically designated gate, FBO operations cater to a wider variety of aircraft types and sizes. Mercury has been able to accommodate up to eleven aircraft at one time on the 1.96-acre site. However, many of the planes being served by the FBO are towed into their parking locations because of a lack of space. Aircraft are parked in close proximity to one another to efficiently use the space that is available. The limited space requires Mercury to constantly reposition aircraft in order to accommodate arriving and departing aircraft. This results in potential safety issues, inefficiencies in operation, increases in emissions, and potential inconvenience to customers. The constrained site also requires Mercury to occasionally park wide-body aircraft at Continental Airlines facilities, further contributing to the same issues.

Even with the rented space discussed above, there are times when Mercury has to turn away clientele due to a lack of space either for aircraft or vehicle parking. These flights are currently going elsewhere at LAX. Mercury routinely turns down LAX originating non-scheduled passenger charter flights because of a lack of vehicle parking. Many of the passengers on a charter flight choose to drive themselves to the FBO. Since no transportation service is provided from remote locations to the FBO, parking is necessary at the FBO facility. Currently, vehicle parking is available for charter flight passengers at the Imperial Terminal parking lot.

Mercury's existing facility does not provide direct access from public streets and clientele and employees are subject to involved procedures to cross the airfield and access the facility. Clientele access the airport via World Way West and pass through a security checkpoint. Upon clearance, clientele must then drive by escort approximately one-eighth of a mile to the Mercury air center building, where parking for drop-off is provided. No overnight parking is available for aircrew, passengers or employees.

The level of activity at the FBO facility fluctuates on a daily and weekly basis. The level of activity tends to follow a weekday business cycle with most of the clientele coming to Los Angeles in private planes for meetings or events. In addition to daily and weekly fluctuations, there can also be seasonal fluctuations. Operational data collected by Mercury at their existing facility for the year 2002, shows that the number of landings and take-offs ranged from a low of one to a maximum of 30 per day.³ (This represents one to 15 aircraft visits per day.) The total landings and take-offs ranged between a low of 304 monthly landings and take-offs in August 2002 to a high of 463 monthly landings and take-offs in January 2002. This results in a monthly average ranging from 10 daily landings and take-offs (5 aircraft visits), which occurred in August 2002, to a high of 15 daily landings and take-offs (7.5 aircraft visits), which occurred in January 2002.

³ Both the low and high occurred in February 2002.

The types of aircraft using the existing Mercury facility vary but can be divided into two categories: corporate aircraft (e.g., Cessna Citation, LearJet 45, Hawker 800, LearJet 60, GulfstreamV, Canadair Challenger); and airline business jets (e.g., Boeing Business Jet-BBJ, Boeing 757, Airbus A-340). The airline business jets, which are similar in size to commercial jets, such as B-727, B-737, B-757, B-747, DC-8, DC-9, DC-10, and A-340, are the largest aircraft served by the Mercury facility. The landings and take-offs for the corporate aircraft account for the majority of the activity, between 94 to 98 percent of the total operations. The total number of corporate aircraft landings and take-offs ranged from 299 to 441 per month in 2002. The total number of landings and take-offs for airline business jets accounted for approximately two to six percent of the total operations. The total number of airline business jet landings and take-offs ranged from five to 28 per month in 2002.

Operational data for general aviation accessing LAX for the year 2002 shows typical annual fluctuations.⁴ Activity ranged from 1,165 landings and take-offs in February to a high of 1,563 landings and take-offs in April. Mercury landings and take-offs represent from 22 to 37 percent of the total general aviation at LAX.

As indicated above, the current facility has a total of 22 vehicular parking spaces. However, since September 11, 2001, employees are prohibited from parking at the FBO. Currently, FBO customers may only temporarily park vehicles during hours that the FBO is open. There is no overnight parking for customer or rental cars. All non-airfield permitted vehicles must be off the FBO leasehold each night before closing. Mercury leases approximately 0.5 acres from American Airlines to accommodate 55 employee parking spaces, 19 of which are for the FBO and 36 for aircraft maintenance.

With regard to the level and type of maintenance to support the FBO, Mercury Air Center LAX provides line maintenance and overnight checks for scheduled airlines. Line maintenance is performed at the terminal gate. Many of the carriers that require overnight checks do not have leaseholds at LAX. Therefore, overnight checks must be performed on other carrier leaseholds due to the lack of space at the current Mercury FBO facility. Routine overnight maintenance, referred to as "A" checks, are performed at other places on the airport using equipment carried in Mercury's service vehicles. Overnight checks are scheduled functional inspections performed from a checklist. The activities include lubrication of moving parts, servicing of fluids, inspection of components, hoses, electrical items and aircraft structure. Lighting and a ground power unit are used during these checks. Mercury currently performs overnight checks for Hawaiian Airlines using other airlines' leaseholds.

⁴ *LAWA Long Range Planning, Forecasting and Analysis, website at <http://www.lawa.org/lax/htmlaf/voltraffic.html>*

Existing Activity on the Project Site

The proposed project would locate the Mercury Air Center FBO adjacent to Imperial Highway near Sepulveda Boulevard (see Figure 2). Two buildings, the B-4 Hangar and Air Freight Building 12, currently occupy the approximately 15-acre site (see Figure 3). The B-4 Hangar, which was built in 1951, contains approximately 67,200 square feet of floor area. The main hanger is 50,000 square feet, with a 30 foot by 40 foot, two-story office area at each end of the hangar providing 17,200 square feet of office space.

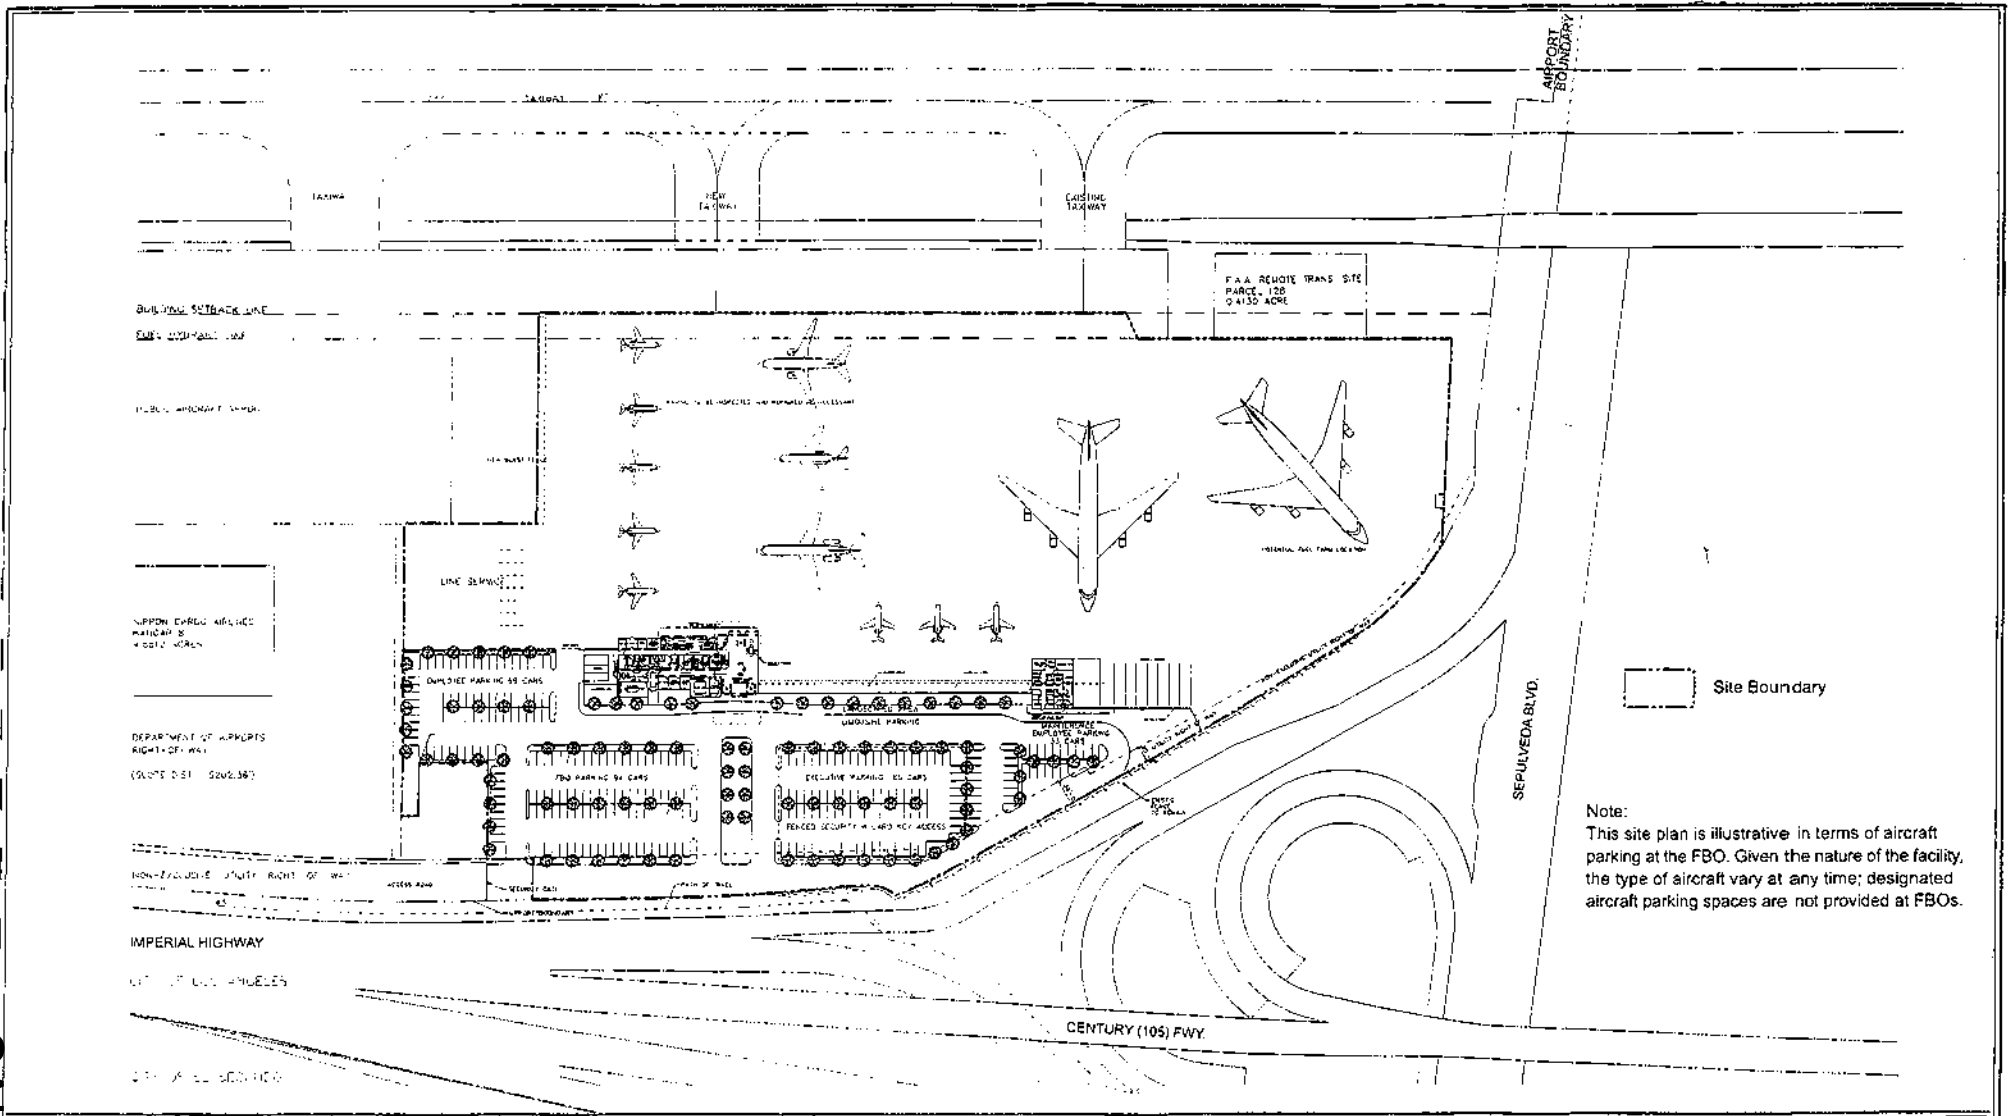

Currently, the Hangar is partially occupied by Airborne Express, a commercial shipping company. Airborne Express has operated at this location since 1993. Airborne Express currently utilizes the offices on the west side of the building and also uses approximately 10,000 square feet of the western portion of the hangar for warehouse space, as well as the ramp area except for the area east of the B-4 Hangar. Airborne's current level of activity ranges from two to four flight operations (commercial) per day, including operations at night. The remainder of the Hangar is vacant.

The second building on the project site, Air Freight Building 12, is located to the west of the Hanger at 6411 West Imperial Highway and is referred to as the Southwest Airlines/LAX Lost and Found building. Currently, the LAWA lost and found office operates at this location. Both buildings ultimately will be demolished. However, Air Freight Building 12 would be used as a temporary FBO during construction of the new facility.

Proposed Mercury Air Center Facilities and Operations

At the outset, the level of aircraft activity at the proposed location would be similar to existing levels of activity for MAG. The majority of the planes would be able to taxi to the location where they would be parked at the FBO rather than being towed because of the increase in space that would result at the proposed site. The increase in space would allow planes to be parked with more space between them. In addition, planes would be parked and generally left in one position rather than having to be moved for other arriving or departing flights. This would increase the overall safety and efficiency of Mercury operations, reduce emissions, and allow MAG to provide better customer service. Figure 4 illustrates a scenario of how planes might park at the new facility. Given the nature of the facility, the types of aircraft vary at any time and designated parking spaces are not provided at FBOs.

LAWA intends to curtail non-scheduled passenger charter flights at the Imperial Terminal, which is located west of the project site. The proposed MAG FBO or other FBO's located at LAX are expected to absorb these flights. The relocation of the non-scheduled passenger charter flights from Imperial to other FBOs would represent an easterly shift in the location of these flights along the southern airport boundary rather than an increase in general

SAL00015

Source: CSA Architects, December 2002.

Figure 4
Illustrative Site Plan

aviation activity levels at the airport. To present a conservative analysis, these flights and potential increases in related flight activity are accounted within the forecasted increase in operations for the project as described below.

Overall general aviation operations activity at LAX has shown a declining trend since peaking in 1978. In 1992, there were 44,016 general aviation operations and by 2000 this had dropped to 17,018 operations at LAX.⁵ It should also be noted that the actual general aviation operations in 2000 fell below the 22,100 general aviation operations projected in the Draft LAX Master Plan. The LAX Master Plan projections, which have been accepted by the FAA, indicate a slight increase in general aviation operations from 22,100 in 2000 (projection) to 22,900 in 2015. Mercury Air Group does not foresee a significant increase in operations over time at the new facility. However, because of the projected increase in general aviation at LAX, an increase in operations is assumed for the proposed Mercury FBO. Using recorded general aviation operations at LAX in 2000 (17,018 operations) as a baseline, forecasts show annual operations at LAX increasing by 5,882, to a total of 22,900 operations by the year 2015. Assuming Mercury captures 50 percent of the general aviation market share, this would result in a daily increase by 2015 of eight operations per day at the proposed Mercury FBO. While the aircraft type and level of activity vary on a daily basis at an FBO, for analysis purposes the flight mix associated with the projected increase in activity is based on the combined most recent annual data available for the fleet mix at Mercury FBO (2002) and Imperial Terminal (2001).

As shown in Figure 4 on page A-10, the proposed approximately 11,530-square foot air center building would be constructed in the western portion of the site. The proposed air center building would provide for necessary increased space, a more functional building plan when compared to the current temporary facility, improved visibility of and by management and more harmonious and pleasing customer service areas. The air center building would house a reception/lobby area, flight planning room, lounge, offices and storage space. The exterior of the air center building includes overhangs that reflect aeronautical concepts (see Figure 5 on page A-12). The building materials would be high quality and durable.

As discussed above, the line service maintenance and overnight checks on general aviation aircraft that are currently conducted by Mercury would be relocated to the extreme western portion of the site, just northwest of the proposed air center building. The new site would allow Mercury to provide overnight maintenance and parking of commercial aircraft, which would occur on the eastern portion of the site. A dedicated aircraft parking space needs to be available in order for such service to occur. However, the first priority would always be to ensure adequate aircraft parking spaces for FBO clientele. The relocation of general aviation and

⁵ The 1992 data is from the LAX Master Plan and the 2001 data is from <http://www.lawa.org/statistics>.

Figure 5
Elevations of the Proposed
Air Center Building

commercial service activities would result in a consolidation of activity that Mercury is currently providing at different locations.

A separate maintenance building would be constructed to the east of the air center building. The approximately 3,400-square foot maintenance building would include offices, training space, and space for aircraft parts storage. In addition, a vehicle and equipment parking area would be provided adjacent to the maintenance building to accommodate the existing Mercury service vehicles and other equipment. In-ground power would be provided and electric-powered ground vehicles would be used. No ground run-up engine testing is proposed.

The parking area for planes using the facility would be to the north of the air center building and maintenance building adjacent to the south airfield complex. The site is currently served by infrastructure for the provision of sewer, water, gas, and electricity. No major upgrades to these facilities are planned.

All new site lighting, including parking lot lighting, would be designed to minimize glare and spill-over onto adjacent, non-airport property through the use of fixtures that would focus and shield illumination. Lighting levels in the parking lot and on the aircraft side of the project would be in conformance with LAWA standards and requirements.

The project site currently has very limited landscaping. Project implementation would substantially increase landscaping through the provision of trees, shrubs, and groundcover along the edges of proposed driveway entry points and in islands within the vehicular parking areas. Landscaping would also be provided around the proposed buildings and at the airside/landside boundaries. All landscaping would, at a minimum, comply with LAWA standards and requirements.

Access and Parking

Access to the site would be from Imperial Highway via California Street, which is located approximately 0.3 miles west of Sepulveda Boulevard. California Street provides access to a frontage road, which parallels Imperial Highway, and leads to the site. Site and adjacent airfield access would be under Mercury Air Center's control.

Parking for the clientele of the FBO facility would be provided along the southern portion of the site. The proposed parking would provide for the consolidation of Mercury parking that exists at the present Mercury site as well as Mercury employee parking at Imperial Terminal. In addition to the parking at the existing facility (22 spaces), Mercury currently rents approximately 0.7 acres at Imperial Terminal to provide 90 spaces, 60 of which are used by fueling employees and 30 spaces are used by air cargo employees. There are also approximately 50 secure parking spaces at Imperial Terminal that are primarily used for non-scheduled passenger charter flights

that will be relocated to the proposed FBO. All of this parking would be consolidated at the new Mercury FBO facility. In total, the project would provide approximately 280 parking spaces divided into four clusters. The easternmost area would contain 33 spaces for maintenance employee parking. To the west of that parking cluster would be a 90-space fenced, security parking area with card key access. A general FBO 90-space parking area would be located to the west of the main entrance. The fourth area would be to the west of the proposed air center building and would contain 66 spaces for employee parking. The additional parking would provide needed parking for the non-scheduled passenger charter flights that would shift from Imperial Terminal to the project site. The proposed parking, which is greater than the parking Mercury currently has available, would provide sufficient parking for Mercury clientele and employees of various Mercury operations. In addition, up to eight spaces would be used for rental cars, which would serve to avoid daily delivery and pickup. As previously stated, the parking areas would be landscaped around the perimeter with trees interspersed within the parking areas. The existing perimeter fencing would be retained and repaired as necessary.

Construction

Construction would begin in 2003, upon receipt of approvals, and would be phased over an approximately 18 month time period. Phase I would involve the renovation of an approximately 5,700-square foot portion of Air Freight Building 12 to serve as a temporary air center building. The B4 Hangar would be demolished. The concrete on the ramp and parking areas would be rehabilitated to the extent required to meet the engineering specifications necessary to accommodate the weight for the types of planes that would use the facility. At this point Mercury Air Group, Inc. would relocate and begin operation at the project site.

Phase II of the project would be the construction of the proposed air center building and maintenance building. All construction activities would occur in accordance with the hours set forth in the City of Los Angeles Municipal Code. Construction could occur between the hours of 7:00 A.M. and 9:00 P.M. on Monday through Friday; between the hours of 8:00 A.M. and 6:00 P.M. on Saturday; and no construction would occur on Sunday.

5.0. NECESSARY APPROVALS

Approvals required for relocation of the Mercury Air FBO facility include, but may not be limited to, the following:

- Approval by LAWA;
- Grading, foundation, and building permits by City of Los Angeles Department of Building and Safety; and
- Any additional actions as may be determined necessary.

ATTACHMENT B
EXPLANATION OF CHECKLIST DETERMINATIONS

I. AESTHETICS. *Would the Project:*

a. Have a substantial adverse effect on a scenic vista?

No Impact. Opportunities for scenic views within the project area and surrounding vicinity vary due to topography and existing development. The project site is developed with two large, industrial-type buildings and pavement. The B-4 Hangar contains 67,200 square feet of floor area and Air Freight Building 12 contains approximately 16,400 square feet of floor area. The project site currently has very limited landscaping and does not contain any unique natural or urban features which contribute to scenic views. In general, public views of the site are limited to vantage points along adjacent roadways and from adjacent commercial properties. The site is visible from Sepulveda Boulevard to the east and from Imperial Highway, which generally runs along the southern boundary of the site. The site is also visible from the El Segundo bluff, which rises at the south side of Imperial Highway and generally runs from Sepulveda Boulevard to Pershing Drive on the west. In addition, the site is visible from the upper stories of an office building and hotel located on the south side of Imperial Highway in El Segundo. As indicated, the buildings on the site are large, industrial-type cargo buildings with little architectural or visual interest. The proposed project would replace these buildings with a new, attractively designed terminal that reflects an aeronautical concept (see Figure 4 of the Project Description). The project would also include a maintenance building and parking areas for automobiles and aircraft. The proposed buildings would represent a reduction in the height and scale of buildings on the site. In addition, the project would introduce landscaping to an area that is currently devoid of landscaping, which would break up the expanse of paving and would provide visual interest. The project would improve the visual quality of the site as seen from Sepulveda Boulevard, Imperial Highway, the bluffs, and adjacent commercial buildings. The project would not have a substantial adverse effect on a scenic vista and therefore, no mitigation measures would be required.

b. Substantially damage scenic resources, including, but not limited to, trees, rock outcroppings, and historic buildings, or other locally recognized desirable aesthetic natural feature within a city-designated scenic highway?

No Impact. The proposed project site does not contain any unique or officially recognized natural, urban, or historic features. In addition, the project site is not located adjacent to a designated scenic highway or vista. The project site is located within the Los Angeles

International Airport (LAX) and consists of industrial buildings and paving. The site is essentially devoid of landscaping and natural features. Consequently, implementation of the proposed project would not damage scenic resources or other locally recognized desirable aesthetic natural features within a city-designated scenic highway or from other non-designated locales. Mitigation measures would not be required.

c. Substantially degrade the existing visual character or quality of the site and its surroundings?

No Impact. The project site is currently developed with large, industrial-type buildings, the B-4 Hangar with 67,200 square feet of floor area and the Air Freight Building 12 with 16,400 square feet of floor area. Along Imperial Highway immediately south of the site, landscaping is very limited. The proposed FBO operation and terminal have been planned and designed to be compatible with existing development at LAX. The approximately 11,530-square foot terminal building would be attractively designed, reflecting an aeronautical concept (see Figure 5 in the Project Description).

The proposed surface parking would be provided in four clusters, which would break up the overall expanse of paving on-site. In addition, the project would substantially increase landscaping on the site through the provision of trees, shrubs, and groundcover along the edges of proposed driveway entry points, adjacent to the terminal building, and in islands within the vehicular parking areas. All landscaping would, at a minimum, comply with LAWA standards and requirements. The proposed landscaping would serve to screen the parking area and other portions of the site from the view of vehicles traveling on Imperial Highway, and from viewpoints along the El Segundo bluff, and from the upper stories of the commercial buildings to the south.

Upon project completion, the proposed buildings, landscaping, and on-site uses would blend harmoniously with existing development and activities within the immediate vicinity. Rather than degrade the existing visual character or quality of the site and its surroundings, the project would represent a substantial upgrade to the visual quality of the site. No mitigation measures would be required.

d. Create a new source of substantial light or glare which would adversely affect day or nighttime views in the area?

Less Than Significant Impact. The B-4 Hangar, which occupies a portion of the site, was built in 1951. For approximately the past 30 years, the Hangar has been used for air cargo. Currently, the B-4 Hangar is partially occupied by Airborne Express, a commercial shipping company. Airborne's current level of activity ranges from two to four flight operations

(commercial) per day, including operations at night. Therefore, the 15-acre site is a source of nighttime lighting similar to other areas along the southern boundary of LAX. The land uses to the south of LAX in the City of El Segundo are separated from the airport by Imperial Highway, Imperial Avenue, and the Imperial Strip, a landscaped open space corridor that parallels Imperial Highway. These three areas create a buffer between the southern boundary of LAX and the land uses located south of LAX and west of Sepulveda Boulevard. The closest light sensitive receptors (residential and hotel uses) are approximately 400 feet south of the project site. The distance from the site to light sensitive receptors (residential and hotel uses) in El Segundo is substantial and as a result, lighting on the site does not currently affect these receptors.

The project would involve demolition of the existing buildings on the site. The new terminal, maintenance building, and parking areas would incorporate lighting. However, all new site lighting, including parking lot lighting, would be designed to minimize glare and spill-over onto adjacent, non-airport property through the use of fixtures that would focus and shield illumination. Lighting levels in the parking lot and on the aircraft side of the project would be in conformance with LAWA standards and requirements. As designed, with conformance to standards, and due to the distance to sensitive receptors, adverse affects from lighting are considered less than significant.

II. AGRICULTURAL RESOURCES. *In determining whether impacts to agricultural resources are significant environmental effects, lead agencies may refer to the California agricultural land evaluation and site assessment model (1997) prepared by the California department of conservation as an optional model to use in assessing impacts on agriculture and farmland. Would the Project:*

- a. **Convert Prime Farmland, Unique Farmland, or Farmland of Statewide Importance, as shown on the maps prepared pursuant to the Farmland Mapping and Monitoring Program of the California Resources Agency, to non-agricultural use?**

No Impact. The project site is located within a developed airport and is surrounded by an urban area. No agricultural resources or operations exist now, or have existed in the recent past at the project site. The proposed project would represent use of the project site in a similar manner to its current uses (i.e., airport-related uses) and would not convert farmland to non-agricultural use. Therefore, no impacts due to conversion of farmland would occur with implementation of the project and no mitigation measures would be required.

b. Conflict the existing zoning for agricultural use, or a Williamson Act Contract?

No Impact. The project site is zoned for Heavy Industrial (M3) use and is located within a developed airport. No agricultural uses presently occur on-site and there are no Williamson Act contracts in effect for the project site or surrounding areas. Therefore, implementation of the proposed project would not result in any conflicts with existing zoning for agricultural use or a Williamson Act contract and no mitigation measures would be required.

c. Involve other changes in the existing environment which, due to their location or nature, could result in conversion of Farmland, to non-agricultural use?

No Impact. There is no farmland in the vicinity of the proposed project site. As discussed in Response No. II.b above, the site is within a developed airport and no farmland would be converted to non-agricultural use. Therefore, implementation of the proposed project would not involve changes in the environment that would result in the conversion of farmland to non-agricultural use and no mitigation measures would be required.

III. AIR QUALITY. *The significance criteria established by the south coast air quality management district (SCAQMD) may be relied upon to make the following determinations. Would the project result in:*

a. Conflict with or obstruct implementation of the SCAQMD or Congestion Management Plan?

No Impact. The project site is located within the 6,600-square mile South Coast Air Basin (Basin). The South Coast Air Quality Management District (SCAQMD) is required, pursuant to the Clean Air Act, to reduce emissions of criteria pollutants for which the Basin is in non-attainment (i.e., ozone, carbon monoxide, and PM₁₀). The Project would be subject to the SCAQMD's Air Quality Management Plan (AQMP). The AQMP contains a comprehensive list of pollution control strategies directed at reducing emissions and achieving ambient air quality standards. These strategies are developed, in part, based on regional population, housing, and employment projections prepared by the Southern California Association of Governments (SCAG).

SCAG is the regional planning agency for Los Angeles, Orange, Ventura, Riverside, San Bernardino and Imperial Counties and addresses regional issues relating to transportation, the

economy, community development and the environment.¹ With regard to air quality planning, SCAG has prepared the Regional Comprehensive Plan and Guide (RCPG), which includes Growth Management and Regional Mobility chapters that form the basis for the land use and transportation control portions of the AQMP, and are utilized in the preparation of the air quality forecasts and consistency analysis included in the AQMP. Both the RCPG and AQMP are based, in part, on projections originating with County and City General Plans. Since the proposed project is consistent with the land use designations of the Los Angeles International Airport Interim Plan and will not increase the amount or nature of FBO operations at LAX, it is considered consistent with the region's AQMP.

With regard to the Congestion Management Plan (CMP), the proposed project will not add 50 or more trips during the A.M. or P.M. weekday peak hours at any CMP intersection. Nor will the project add 150 or more trips during the A.M. or P.M. weekday peak hours at any CMP mainline freeway monitoring location (see Section XV., Transportation/Circulation). As indicated in the Traffic Technical Memorandum, which is contained in Appendix C, the project would generate 6 net peak hour trips. (Even with a worst case assumption of a 25 percent increase in employees, as indicated in the Traffic Technical Memorandum, with this assumption the project would generate 18 net peak hour trips.) Thus, the project would not exceed any CMP thresholds. No impacts associated with implementation of the AQMP or CMP would result, and no mitigation measures would be required.

b. Violate any air quality standard or contribute substantially to an existing or projected air quality violation?

Less Than Significant Impact. As discussed above, the project site is located within the Basin, which is characterized by relatively poor air quality. State and federal air quality standards are often exceeded in many parts of the Basin.

The proposed project would contribute to regional air pollutant emissions during construction and long-term operation. The SCAQMD has established methodologies to quantify air emissions associated with general construction activities such as on-site equipment operation, fugitive dust (from demolition and site preparation activities), and mobile emissions (from construction worker and haul truck travel). Demolition would produce equipment and fugitive dust emissions, as would site grading and construction activities. As indicated in Table 1 on page B-6, construction emissions are anticipated to fall below SCAQMD significance thresholds, resulting in a less than significant impact to regional air quality.² In addition, all construction

¹ SCAG serves as the federally designated metropolitan planning organization (MPO) for the southern California region.

² Please refer to Appendix A for air quality worksheets prepared by PCR Services Corporation, April 2003.

Table 1

ESTIMATED WORST CASE CONSTRUCTION EMISSIONS BY PHASE

Construction Phase	Pollutant Emissions (Pounds per Day)				
	CO	ROC	NO _x	SO _x	PM ₁₀ ^a
Demolition (11 weeks) ^b	39	10	84	6	14
Site Preparation (1 week)	3	<1	6	1	1
Building Erection/Finishing (20 weeks) ^c	40	19	81	4	9
Maximum Construction Emissions	40	19	84	6	14
SCAQMD Significance Threshold	550	75	100	150	150
Maximum Construction Emissions less SCAQMD Significance Threshold Over (Under)	(510)	(56)	(16)	(144)	(136)

^a Fugitive dust emissions assume compliance with SCAQMD Rule 403.

^b Demolition debris may be recycled or reused on-site which would require the use of crushing equipment. Daily emissions associated with these activities would result in similar emissions as provided above and would remain below the SCAQMD significance threshold.

^c The 20 weeks includes 18 days for architectural coatings and 35 days for asphalt paving.

Source: PCR Services Corporation, April 2003. Construction emission calculation worksheets are included in Appendix A.

activities would comply with SCAQMD Rule 403 fugitive dust control measures. Compliance with these measures would further ensure that the short-term air quality impacts of the proposed project due to demolition, grading, and construction activities would be less than significant.

The SCAQMD has also established methodologies to quantify air emissions associated with long-term project operations. As discussed below in Section XV, Transportation/Circulation, the proposed project would generate 6 net peak hour vehicle trips (as a worst case scenario, assuming a 25 percent increase in employees, the trip would generate 18 net peak hour trips). The 6 net peak hour trips are not really new trips, but rather are trips that would relocate from the west side to the south side of the airport. There would be a minimal increase in mobile source emissions. In addition, the proposed project would not impact local one-hour or eight-hour carbon monoxide (CO) concentrations, since the project would not meaningfully affect existing traffic volumes or circulation patterns.

As discussed in Attachment A, Project Description, based on general aviation projections for the year 2015, the proposed project could result in a slight increase in the level of aircraft activity compared with the existing levels of activity at Mercury FBO and at Imperial Terminal

relative to non-scheduled passenger charter flights. Assessment of airport-related air emissions was conducted in accordance with the FAA guidelines and SCAQMD's Air Quality Handbook.³ The Emissions and Dispersion Modeling System (EDMS, version 4.0) was used to generate an inventory of emissions from aircraft and ground service equipment (GSE) associated with this additional activity. (The flight mix associated with the increase in activity is based on the most recent annual data available for the fleet mix at Mercury FBO (2002) and Imperial Terminal (2001).) EDMS was developed by the Federal Aviation Administration in cooperation with the United States Air Force and is the preferred model for analyzing civilian and military airport emissions. The model results indicate that aviation-related uses for the project would generate 139 lbs/day of CO, 43 lbs/day of ROC, 48 lbs/day of NO_x, one lb/day of PM₁₀, and four lbs/day of SO_x. These emissions are incorporated into the regional operational emissions for the project, presented in Table 2 on page B-8, and are detailed in Appendix A. The EDMS input and output files are also provided in Appendix A.

As discussed in Attachment A, Project Description, Mercury provides line maintenance and overnight checks for general aviation and scheduled airlines. Routine overnight maintenance, referred to as "A" checks, are scheduled functional inspections performed from a checklist. The activities include lubrication of moving parts, servicing of fluids, inspection of components, hoses, electrical items and aircraft structure. Lighting and a ground power unit are used during these checks. The level of proposed service maintenance would be similar as to existing levels for MAG and, therefore, emissions generated from small amounts of lubricants, solvents, and paints would not be anticipated to change. Project-related operational emissions generated by stationary sources (due to electricity and natural gas consumption) were calculated based on SCAQMD's CEQA Air Quality Handbook, Table A9-11.⁴ Compared to existing conditions, implementation of the proposed project would result in a net decrease in building square footage and related stationary-source emissions on the project site due to the demolition of two existing buildings. However, a conservative estimate of stationary source emissions has been provided in this assessment and, therefore, emissions due to electricity and natural gas from project-related buildings are calculated as new emissions and are included in Table 2.

As indicated in Table 2 on page B-8, the overall increase in pollutants (mobile sources and stationary sources combined) associated with the proposed Mercury FBO would be below SCAQMD significance thresholds. As such, the resulting stationary and mobile source emissions generated during operation of the project would have less than significant impacts on air quality and no mitigation measures would be required.

³ Federal Aviation Administration, "Airport Environmental Handbook," *FAA Order 5050.4A*, October 8, 1985; "Policies and Procedures for Considering Environmental Impacts," *FAA Order 1050.1D*, December 5, 1986; and *Air Quality Procedures for Civilian Airports and Air Force Bases*, 1997.

⁴ No new stationary equipment (e.g., boilers and generators) is proposed as part of the project.

Table 2

PROJECT OPERATIONAL EMISSIONS

Project Source	Pollutant Emissions (Pounds per Day)				
	CO	ROC	NO _x	SO _x	PM ₁₀
Mobile Sources	---	---	---	---	---
Stationary Sources (electricity consumption) ^a	<1	<1	<1	<1	<1
Aviation Emissions ^b	139	43	48	4	<1
Total Project Emissions	139	44	49	4	<1
SCAQMD Significance Threshold	550	55	55	150	150
Project Emissions less SCAQMD Significance Threshold	(411)	(11)	(6)	(146)	(149)

^a Based on electricity consumption taken from the SCAQMD's CEQA Air Quality Handbook.

^b Based on FAA's EDMS preferred model for analyzing civilian and military airport emissions.

Source: PCR Services Corporation, April 2003. Supporting calculations are included in Appendix A.

c. Result in a cumulatively considerable net increase of any criteria pollutant for which the air basin is non-attainment (ozone, carbon monoxide, & PM₁₀) under an applicable federal or state ambient air quality standard?

Less Than Significant Impact. The project site is located in a region that is classified as non-attainment for ozone, CO, and PM₁₀. Construction-period emissions would not be cumulatively considerable, as daily emissions would fall below the SCAQMD significance thresholds. With regard to the project's long-term operational emissions cumulative effect on regional air quality, the proposed project is anticipated to have negligible effect on regional emissions and result in a net decrease in stationary-source emissions. The project would not contribute to a cumulatively considerable net increase in ozone, carbon monoxide or PM₁₀. No mitigation measures are necessary.

d. Expose sensitive receptors to substantial pollutant concentrations?

No Impact. The project site and the surrounding area contain airport and transportation uses. The closest residential uses are located south of the project site across Imperial Highway. The proposed project does not contain any SCAQMD permitted stationary emissions sources (e.g., boilers, emergency generators, spray-booths). In general, the primary pollutant of concern with regard to harmful pollutant concentrations resulting from this type of project is carbon monoxide. As described in Response No. III.b. above, construction and operation of the proposed uses would not result in any substantial local or regional air pollution impacts and,

therefore, would not expose any nearby sensitive receptors to severe air pollution conditions. No impacts would occur, and no mitigation measures would be required.

e. Create objectionable odors affecting a substantial number of people?

No Impact. No objectionable odors are expected as a result of project construction or operation. Small quantities of chemicals, solvents, and petroleum products would be used during maintenance activities, which would take place outside the enclosed buildings. Usage of these products would comply with the manufacturer's recommended storage and handling specifications. Odorous emissions from these products would be negligible and no impacts are anticipated. Therefore, no mitigation measures would be required.

IV. BIOLOGICAL RESOURCES. *Would the project:*

a. Have a substantial adverse effect, either directly or through habitat modification, on any species identified as a candidate, sensitive, or special status species in local or regional plans, policies, or regulations by the California Department of Fish and Game or U.S. Fish and Wildlife Service?

No Impact. The project site is located within a developed airport and an urbanized area and is currently developed with airport facilities. Although small portions of the project site perimeter and small areas adjacent to the existing buildings have been landscaped, largely non-native plant species occupy the area. However, other areas within the airport boundary contain plant and animal species as well as habitats identified as sensitive. The western portion of the airport contains habitat for the El Segundo blue butterfly, Riverside fairy shrimp, Lewis' evening primrose, and the California spineflower. In addition, there have been American Peregrine falcon sightings within and surrounding the airport boundary.⁵ None of the identified sensitive plant or animal species have been identified on the proposed project site or immediate vicinity. Suitable habitat for sensitive mammal, reptile, amphibian, or fish species do not exist on the project site. Given the limited on-site animal and plant life and the urbanized nature of the project site and surrounding area, the proposed project would not have a substantial adverse affect on any identified candidate, sensitive, or special status species. Therefore, no impacts to candidate, sensitive, or special status species would occur and no mitigation measures would be required.

⁵ U.S. Department of Transportation Federal Aviation Administration and City of Los Angeles, Draft Environmental Impact Statement/Environmental Impact Report, Los Angeles International Airport Proposed Master Plan Improvements, Section 4.10-4.11, January 2001.

- b. Have a substantial adverse effect on any riparian habitat or other sensitive natural community identified in the City or regional plans, policies, regulations by the California Department of Fish and Game or U.S. Fish and Wildlife Service?**

No Impact. As discussed in Response No. IV.a, the project site has been previously developed as part of an airport and is located within an urbanized area. The project site does not contain any riparian habitat or other sensitive natural communities. Therefore, implementation of the proposed project would not have a substantial adverse effect on any riparian habitat or other sensitive natural community and no mitigation measures would be required.

- c. Have a substantial adverse effect on federally protected wetlands as defined by Section 404 of the Clean Water Act (including, but not limited to, marsh vernal pool, coastal, etc.) Through direct removal, filling, hydrological interruption, or other means?**

No Impact. As discussed in Response No. IV.a, the project site has been previously developed as part of an airport and is located within an urbanized area. The project does not contain any wetlands as defined by Section 404 of the Clean Water Act. Therefore, implementation of the proposed project would not have an adverse effect on federally protected wetlands and no mitigation measures would be required.

- d. Interfere substantially with the movement of any native resident or migratory fish or wildlife species or with established native resident or migratory wildlife corridors, or impede the use of native wildlife nursery sites?**

No Impact. As discussed in Response No. IV.a, the project site has been previously developed as part of an airport and is located within an urbanized area. The project site does not contain native resident or migratory species or native nursery sites. Therefore, implementation of the proposed project would not interfere with the movement of any native resident or migratory fish or wildlife species or with established native resident or migratory wildlife corridors, or impede the use of native nursery site and no mitigation measures would be required.

- e. Conflict with any local policies or ordinances protecting biological resources, such as tree preservation policy or ordinance (e.g., oak trees or California walnut woodlands)?**

No Impact. As discussed in Response No. IV.a, the project site has been previously developed within an airport and is located within an urbanized area. Furthermore, the project site does not contain any significant biological resources, such as oak trees or California walnut woodlands, protected by local policies or ordinances. Therefore, the proposed project would not

conflict with local policies or ordinances protecting biological resources and no mitigation measures would be required.

f. Conflict with the provisions of an adopted Habitat Conservation Plan, Natural Community Conservation Plan, or other approved local, regional, or state habitat conservation plan?

No Impact. As discussed in Response No. IV.a, the project site is within a developed airport and within an urbanized area. Although the Dunes Specific Plan Area is a designated Los Angeles County Significant Ecological Area (which contains the El Segundo Blue Butterfly Habitat Restoration Area), the area is not in close proximity and is located at the far western portion of the airport. There is no adopted Habitat Conservation Plan, Natural Community Conservation Plan, or other approved local, regional, or state habitat conservation plan that includes the project site or immediate vicinity. Therefore, implementation of the proposed project would not conflict with the provisions of any adopted conservation plan or other similar plan and no mitigation measures would be required.

V. CULTURAL RESOURCES. *Would the project:*

a. Cause a substantial adverse change in significance of a historical resource as defined in State CEQA §15064.5?

No Impact. Section 15064.5(a)(3) of the CEQA Guidelines generally defines historical significance as any object, building, structure, site, area, place, record, or manuscript determined to be historically significant or significant in the architectural, engineering, scientific, economic, agricultural, educational, social, political, military, or cultural annals of California. Historical resources are further defined as being associated with significant events, important persons, or distinctive characteristics of a type, period or method of construction; representing the work of an important creative individual; or possessing high artistic values.

The proposed project includes the demolition of the B-4 Hangar and Air Freight Building 12. The B-4 Hangar was constructed in 1951 and is approximately 50 years old. The timing of construction of the Air Freight Building 12 is not known. However, Air Freight Building 12 does not appear in a 1976 aerial of LAX, but is apparent in a 1994 aerial. Historic and architectural resources surveys were conducted in 1995, 1998 and 2000 of LAWA owned properties and other areas in association with the preparation of the EIR/EIS for the Los Angeles International Airport Master Plan. The findings of the surveys indicate that four buildings within LAX are considered potentially significant historic/architectural resources. These buildings are: Hangar One (listed on National Register); Theme Building (eligible for National Register);

WWII Munitions Storage Bunker (eligible for National Register); and Intermediate Terminal Complex (eligible for the California Register).⁶ The existing buildings on the project site are neither historically significant nor significant in terms of their architecture. As such, no adverse impacts to significant historical resources would occur and no mitigation measures would be necessary.

b. Cause a substantial adverse change in significance of an archaeological resource pursuant to State CEQA §15064.5?

No Impact. No prehistoric or historic archaeological sites have been identified within the project site, nor have unique or important prehistoric or historic archaeological resources been encountered within the immediate project vicinity. The project site, located within LAX, is developed and has been subject to extensive disruption over the years. Thus, any surficial archaeological resources, which may have existed at one time have likely been removed. The project would involve only limited excavation at shallow depths. With no surficial archaeological resources existing on the site, and previous development and grading, the proposed project is not expected to cause a substantial adverse change in the significance of an archaeological resource pursuant to Section 15064.5. Therefore, the project would not result in an impact and no mitigation measures would be required.

c. Directly or indirectly destroy a unique paleontological resource or site or unique geologic feature?

No Impact. The LAX property lies in the northwestern portion of the Los Angeles Basin, a broad structural syncline with a basement of older igneous and metamorphic rocks overlain by thick younger marine and terrestrial deposits.⁷ The proposed project site is relatively flat and is underlain by older eolian deposits of Quaternary age. Any surficial paleontological resources, which may have existed at one time, have likely been previously disturbed by past development activities. Therefore, the topmost layers of soil in the project area are not likely to contain substantive fossils. While a records search identified the presence of two vertebrate fossil occurrences with the LAX study area, the fossils were found at depths ranging from 13 to 70 feet. While excavation into the deeper deposits could potentially uncover vertebrate fossil remains, the project would involve only limited excavation at depths less than three feet. Therefore, the proposed project is not expected to directly or indirectly destroy a unique paleontological resource or site or geologic feature. No mitigation measures would be required.

⁶ Draft EIR/EIS for the LAX Proposed Maser Plan Improvements, January 2001.

⁷ Ibid.

d. Disturb any human remains, including those interred outside of formal cemeteries?

No Impact. The project site has been previously developed as part of an airport and is located within an urbanized area. Within the project area, traditional burial resources would likely be associated with the Native American group known as the Gabrielino. Based on previous surveys conducted at LAX and on record searches completed in 1995, 1997, and 2000 for the LAX Master Plan, no traditional burial sites have been identified within the project site or in the vicinity. The project would involve surficial grading and trenching. Therefore, it is not anticipated that the proposed project would disturb any human remains and no mitigation measures would be required.

VI. GEOLOGY AND SOILS. *Would the project:*

- a. Exposure of people or structures to potential substantial adverse effects, including the risk of loss, injury or death involving:**
- i. Rupture of a known earthquake fault, as delineated on the most recent Alquist-Priolo Earthquake Fault Zoning Map issued by the State Geologist for the area or based on other substantial evidence of a known fault? Refer to Division of Mines and Geology Special Publication 42.**

Less Than Significant Impact. Fault rupture is the surface displacement that occurs along the surface of a fault during an earthquake. The City of Los Angeles is affected by the Alquist-Priolo Earthquake Fault Zones as listed in Special Publication 42.⁸ While the site is located within the seismically active southern California region, it is not located within an Alquist-Priolo Special Study Zone or a Fault Rupture Study Area. Geotechnical literature indicates that the Charnock Fault, a potentially active fault, may be located near or through eastern portions of LAX property. However, a recent evaluation conducted for the LAX Master Plan EIS/EIR indicates that the Charnock Fault does not displace Holocene deposits and is considered to have low potential for surface rupture independently or in conjunction with movement on the Newport-Inglewood Fault Zone. Therefore, impacts to people or structures resulting from rupture of a known earthquake fault are considered less than significant and no mitigation measures are required.

⁸ California Department of Conservation California Geological Survey, Table 4 Cities and Counties Affected by Alquist-Priolo Earthquake Fault Zones as of May 1, 1999, <http://www.consrv.gov/cgs/rghm/ap/affected.htm>.

ii. Strong seismic ground shaking?

Less Than Significant Impact. The project site is located in the seismically active southern California region; however, there is no evidence of faulting on the site, and it is not located within an Alquist-Priolo Special Study Zone or a Seismic Hazard Zone, as delineated by the California Geological Survey.⁹ As part of the proposed project, new construction would meet Uniform Building Code (UBC) and City of Los Angeles building code requirements and modern standards for seismic safety. Since the proposed project would comply with UBC and City of Los Angeles building code requirements, potential impacts associated with strong seismic ground shaking would be less than significant and no mitigation measures would be required.

iii. Seismic-related ground failure, including liquefaction?

No Impact. Liquefaction is a phenomenon where loose, saturated, granular soils lose their inherent shear strength due to excess water pressure that builds up during repeated movement from seismic activity. Factors that contribute to the potential for liquefaction include a low relative density of granular materials, a shallow groundwater table, and a long duration and high acceleration of seismic shaking. Liquefaction usually results in horizontal and vertical movements from lateral spreading of liquefied materials and post-earthquake settlement of liquefied materials. Based on the City's Safety Element, the proposed project site is not located within an area that is highly susceptible to liquefaction.¹⁰ In addition, the Official Map of Seismic Hazard Zones, published by the California Geological Survey (formerly, Division of Mines and Geology), indicates that the project site is not within a liquefaction zone.¹¹ Therefore, development of the proposed project would not expose people or structures to significant impacts involving seismic ground-related failure, including liquefaction and no mitigation measures are required.

iv. Landslides?

No Impact. The project site and vicinity are relatively flat, and are surrounded by existing urban and airport development. Furthermore, the City of Los Angeles Landslide Inventory and Hillside Areas map does not identify any areas in the vicinity of the project site

⁹ California Department of Conservation California Geological Survey (formerly, Division of Mines and Geology), State of California Seismic Hazard Zones Venice Quadrangle Official Map, Released March 25, 1999.

¹⁰ City of Los Angeles Planning Department, Safety Element of the City of Los Angeles General Plan, Exhibit B, Areas Susceptible to Liquefaction In the City of Los Angeles, October 1993.

¹¹ California Department of Conservation California Geological Survey (formerly, Division of Mines and Geology), State of California Seismic Hazard Zones Venice Quadrangle Official Map, Released March 25, 1999.

that contain unstable slopes which may be prone to seismically-produced landslides.¹² Implementation of the proposed project would not result in the exposure of people or structures to the risk of landslides during a seismic event. No impacts resulting from landslides would occur and no mitigation measures would be required.

b. Result in substantial soil erosion or the loss of topsoil?

No Impact. The potential for soil erosion on the project site is low due to the generally level topography of the project site. In addition, the majority of the site is developed with buildings and covered with impervious surfaces. Although the existing B-4 Hanger and Air Freight Building 12 would ultimately be demolished, the entire project site would not be exposed to potential soil erosion at one time. Air Freight Building 12 would be used as a temporary FBO building during construction of the portion of the site containing the existing B-4 Hangar. Project construction could require the removal of some of the existing asphalt on-site. However, the amount of asphalt to be removed is expected to be minimal. The slabs underneath the existing buildings, as well as pavement would be removed only as determined to be necessary. In addition, soil moved during grading activities required for the proposed project would be balanced on the project site. In addition, conformance with City Building Code Sections 91.7000 through 91.7016, which include construction requirements for grading, excavation, and use of fill, would reduce the potential for wind or waterborne erosion. In addition, the Los Angeles Building Code requires an erosion control plan that is reviewed by the Department of Building and Safety prior to construction if grading exceeds 200 cubic yards and occurs during the rainy season (between November 1 and April 15). Therefore, project impacts related to soil erosion are anticipated to be minimal and no mitigation measures would be required.

c. Be located on a geologic unit or soil that is unstable, or that would become unstable as a result of the project, and potential result in on- or off-site landslide, lateral spreading, subsidence, liquefaction, or collapse?

No Impact. The project site and vicinity are relatively flat and do not contain unstable slopes that are prone to on- or off-site landslides or lateral spreading. Furthermore, the project site is underlain by older eolian deposits of Quaternary age, which have low liquefaction susceptibility.¹³ With implementation of requirements associated with UBC and City of Los Angeles building code requirements, other City and County regulations, and project design

¹² City of Los Angeles Planning Department, *Safety Element of the City of Los Angeles General Plan, Exhibit C, Landslide Inventory & Hillside Areas In the City of Los Angeles, June 1994.*

¹³ California Department of Conservation California Geological Survey (formerly, Division of Mines and Geology), *Seismic Hazard Evaluation of the Venice 7.5-Minute Quadrangle, Los Angeles County, California, 1998, page 9 and plate 1.1.*

features, no significant impacts are anticipated to occur due to unstable geologic or soil conditions. No mitigation measures would be required.

d. Be located on expansive soil, as defined in Table 18-1-B of the Uniform Building Code (1994), creating substantial risks to life or property?

No Impact. Expansive soils are typically composed of certain types of silts and clays that have the capacity to shrink or swell in response to changes in soil moisture content. The project site is not located in an area with expansive soil. Since construction would occur in accordance with the Los Angeles Building Code Sections 91.7000 through 91.7016, which include construction requirements for grading, excavation, and foundation work, the potential for hazards to occur as a result of expansive soils would be minimized. Therefore, project implementation would not result in significant impacts associated with expansive soils and no substantial risks to life or property would occur. No mitigation measures would be necessary.

e. Have soils incapable of adequately supporting the use of septic tanks or alternative wastewater disposal systems where sewers are not available for the disposal of wastewater?

No Impact. The proposed project site is located in an urbanized area where wastewater infrastructure is currently in place. The proposed project would not use septic tanks or alternative wastewater disposal systems. Therefore, the ability of on-site soils to support septic tanks or alternative wastewater systems would not be relevant to the proposed project and no mitigation measures would be required. Refer to Response No. XVI.b for a discussion of wastewater flows associated with the proposed project.

VII. HAZARDS AND HAZARDOUS MATERIALS. *Would the project:*

a. Create a significant hazard to the public or the environment through the routine transport, use, or disposal of hazardous materials?

Less Than Significant Impact. Project implementation would result in construction of a new terminal and associated uses on-a site currently developed with cargo facilities. Construction activities associated with the new structures would involve the use of potentially hazardous materials, including vehicle fuels, oils, and transmission fluids. However, all potentially hazardous materials necessary for the construction of the project would be contained, stored, and used in accordance with manufacturers' instructions and handled in compliance with applicable standards and regulations.

Due to the age of the existing structures on the project site, the potential for encountering asbestos containing materials (ACM) and lead based paint (LBP) during demolition exists. The use of ACM and LBP was unregulated until 1979. A Phase I Baseline Environmental Site Assessment of the B-4 Hangar indicates that ACM and LBP exist in the Hangar.¹⁴ Therefore, an ACM survey would be required in accordance with SCAQMD Rule 1403 and a LBP survey would be conducted to document worker exposure levels per California Occupational Safety and Health Administration (Cal-OSHA) Construction Safety Orders, California Code of Regulations, Title 8, Section 1532.1. Any removal of these materials from the buildings on the project site would be performed by a State-certified lead or asbestos containment contractor. Mandatory compliance with applicable standards and procedures would reduce risks associated with ACM and LBP to acceptable levels. Therefore, significant impacts associated with exposure to asbestos or lead based paint would not occur. As such, construction of the proposed project would not create a significant hazard to the public or the environment through the transport, use, or disposal of hazardous materials, and no mitigation measures would be required.

FBO activities typically involve the use and storage of potentially hazardous materials in the form of fuels, oils, and transmission fluids for the aircraft. In addition, cleaning solvents associated with the terminal and pesticides for landscaping would be used on the project site. All potentially hazardous materials would be contained, stored, and used in accordance with manufacturers' instructions and handled in compliance with applicable standards and regulations. Thus, project implementation would not create a significant hazard to the public or the environment through the routine transport, use, or disposal of hazardous materials, and no mitigation measures would be necessary.

b. Create a significant hazard to the public or the environment through reasonably foreseeable upset and accident conditions involving the release of hazardous materials into the environment?

Less Than Significant Impact. Numerous safeguards are required by law, or are otherwise provided in the hazardous materials handling processes to minimize any hazards to people or property. Provisions relating to the generation, transport, treatment, storage, and disposal of hazardous materials are contained in the federal Resource Conservation and Recovery Act, the federal Toxic Substances Control Act, the California Hazardous Waste Control Law, the Uniform Fire Code, the Hazardous Materials Transportation Act of 1994, and numerous other federal, state and local regulations. These safeguards are designed to minimize the potential for and the effects from an accident if one were to occur. In addition to the many safeguards required by law, LAWA and tenants of LAX maintain Emergency Response and

¹⁴ Earth Tech, Inc., Phase I Baseline Environmental Site Assessment, B-4 Hangar, ABX Air Inc., 6401 West Imperial Highway, April 2002.

Evacuation Plans to minimize the potential for an accident and to minimize the effects of an accident, if one occurs. The project would not change the nature of or meaningfully increase handling of hazardous materials as the site would continue to serve aircraft with associated support facilities. With a new emphasis on passenger service rather than cargo, the potential for an accidental release of hazardous materials would likely be reduced. Considering the safeguards required by law and maintenance of Emergency Response and Evacuation Plans, impacts associated with upset or accident conditions involving hazardous materials are considered to be less than significant and no mitigation measures would be required.

c. Emit hazardous emissions or handle hazardous or acutely hazardous materials, substances, or waste within one-quarter mile of an existing or proposed school?

No Impact. There are no schools located or proposed within one-quarter mile of the project site. Furthermore, the project would not change the nature of or meaningfully increase hazardous emissions or the handling of hazardous materials as aircraft would continue to use the site and be served by site facilities.

d. Be located on a site which is included on a list of hazardous materials sites compiled pursuant to Government Code Section 65962.5 and, as a result, would it create a significant hazard to the public or the environment?

No Impact. The site does not have any known existing soil or groundwater contamination or remediation underway.¹⁵ Four underground storage tanks (USTs) were removed from the site in 2001. Soils samples, which were collected from below the USTs, were analyzed for total petroleum hydrocarbons (TPH) as gasoline, TPH as diesel, and methyl tert-butyl ether (MTBE). TPE (gasoline or diesel) and MTBE were not detected above the laboratory reporting limits.¹⁶ As such, no impact would occur associated with project implementation since the project would not occur on a site that is included on a list of hazardous materials sites. Therefore, the project would not create a significant hazard to the public or environment and mitigation measures would not be required.

¹⁵ Draft EIR/EIS for the LAX Proposed Maser Plan Improvements, January 2001 and Camp Dresser & McKee Inc., Soil Contamination Assessment Report, August 4, 1999.

¹⁶ Camp Dresser & McKee Inc., UST Closure Report: Asiana Facility, 6401 Imperial Highway, May 2002.

- e. **For a project located within an airport land use plan or, where such a plan has not been adopted, within two miles of a public airport or public use airport, would the project result in a safety hazard for people residing or working in the project area?**

Less Than Significant Impact. Numerous safeguards are required by law to minimize the potential for and the effects from an accident if one were to occur. FAA's Airport Design Standards establish, among other things, land use related guidelines to protect people and property on the ground, including establishment of safety zones that keep areas near runways free of objects that could interfere with aviation activities. City of Los Angeles Ordinance No. 132,319 regulates building height limits and land uses within the Hazard Area established by the Planning and Zoning Code to protect aircraft approaching and departing from LAX from obstacles. In addition to the many safeguards required by law, LAWA and tenants of LAX maintain Emergency Response and Evacuation Plans that also serve to minimize the potential for and the effects of an accident. The project would relocate the existing FBO from one area within the airport to an area that is currently used for air cargo freight. Mercury Air Group would modify their Emergency Response and Evacuation Plan for the new location. In addition, the relocation of Mercury FBO would consolidate the FBO activity on the south side of the airfield, since Garrett Aviation Service (another FBO facility) is located to the east of the project site across Sepulveda Boulevard. This consolidation would contribute to overall airport safety since it would minimize confusion for transient pilots as to their parking location relative to the runway complex. Additionally, the consolidation would eliminate runway crossings by mechanics re-positioning general aviation aircraft from Mercury FBO to Garrett Aviation Service FBO and vice-versa.¹⁷ As such, the proposed project would result in a less than significant impact with regard to a safety hazard for people working in the project area. No mitigation measures would be required.

- f. **For a project within the vicinity of a private airstrip, would the project result in a safety hazard for the people residing or working in the area?**

No Impact. The project site is not located within the vicinity of a private airstrip but rather within a public airport. See Response to Comment VII., e., above.

- g. **Impair implementation of or physically interfere with an adopted emergency response plan or emergency evacuation plan?**

No Impact. LAWA and tenants of LAX maintain Emergency Response and Evacuation Plans to minimize the potential for and the effects of an accident, should one occur.

¹⁷ Written communication, Raymond Jack, LAX Airfield Operations, October 28, 2002.

Construction activities and staging areas for the proposed project would be confined to the site. Since the site is generally accessible from all sides, access by emergency vehicles to the project site would not be physically impaired during construction. During operation of the project, the site would also be accessible from the road to the south as well as from other areas of LAX. In addition, Mercury Air Group, as a tenant at LAX, would modify the existing Emergency Response and Evacuation Plan for the proposed site and would continue to maintain an Emergency Response and Evacuation Plan. As such, construction and operation of the proposed project would not impair implementation of or physically interfere with an adopted emergency response plan or emergency evacuation plan. No mitigation measures would be required.

- h. Expose people or structures to a significant risk of loss, injury or death involving wildland fires, including where wildlands are adjacent to urbanized areas or where residences are intermixed with wildlands?**

No Impact. The project site and vicinity are predominantly paved and/or developed. There are no fire hazard areas containing flammable brush, grass, or trees on or adjacent to the project site. Furthermore, the proposed project site is not within a City of Los Angeles Wildfire Hazard Area, as delineated in the Safety Element of the General Plan.¹⁸ Therefore, implementation of the proposed project would not result in the exposure of people or structures to hazards associated with wildland fires and no mitigation measures would be required.

VIII. HYDROLOGY AND WATER QUALITY. *Would the proposal result in:*

- a. Violate any water quality standards or waste discharge requirements?**

No Impact. The agency with jurisdiction over water quality at LAX is the Los Angeles Regional Water Quality Control Board (LARWQCB). The Clean Water Act (CWA) prohibits the discharge of pollutants to waters of the United States from any point source unless the discharge is in compliance with a National Pollutant Discharge Elimination System (NPDES) permit. In accordance with the CWA, the airport is within the region covered by NPDES Permit No. CAS614001 issued by the LARWQCB on July 15, 1996. Construction of the proposed project would occur on a site that serves aircraft and is currently developed with cargo buildings and related facilities. Demolition of these buildings and possible reconditioning or replacement of airfield paving would not meaningfully alter the existing drainage pattern or result in substantial erosion or siltation. In addition, project implementation would not alter the surface water runoff quantities of the site. Project construction would occur in accordance with

¹⁸ *City of Los Angeles Planning Department, Safety Element of the City of Los Angeles General Plan, Exhibit D, Selected Wildfire Hazard Areas In the City of Los Angeles, April 1996.*

applicable discharge requirements as set forth by the Los Angeles Regional Water Quality Control Board (LARWQCB). As such, project construction would not result in adverse impacts on surface water quality and no mitigation measures would be necessary.

Similar to existing conditions on the site, runoff from the proposed surface parking lot areas and the aircraft taxiway would contain heavy metals, oil, and grease. As part of the proposed project, implementation of the Standard Urban Storm Water Mitigation Plan (SUSMP) would occur. Under SUSMP, the project would be required to ensure that post-development peak storm water runoff discharge rates would not exceed the estimated pre-development rates where the increased peak storm water discharge rate would result in increased potential for downstream erosion. SUSMP requirements also include, but are not limited to, the following: minimizing stormwater pollutants of concern; providing storm drain system stenciling and signage; containing properly designed outdoor material storage areas; containing properly designed trash storage areas; and providing proof of ongoing Best Management Practice (BMP) maintenance. Specifically, parking lots on the project site could be required to: reduce impervious land coverage of parking areas; infiltrate runoff before it reaches the storm drain system; treat runoff before it reaches the storm drain system; treat to remove oil and petroleum hydrocarbons; and ensure adequate operation and maintenance of treatment systems. Since the project would implement SUSMP requirements, project operation would not result in adverse water quality impacts, and no mitigation measures would be necessary.

Since the project would comply with all LARWQCB requirements regarding water quality standards and waste discharge requirements, the construction and operation of the project would not violate any water quality standards or waste discharge requirements.

- b. Substantially deplete groundwater supplies or interfere with groundwater recharge such that there would be a net deficit in aquifer volume or a lowering of the local groundwater table level (e.g., the production rate of pre-existing nearby wells would drop to a level which would not support existing land uses or planned land uses for which permits have been granted)?**

No Impact. The project site is located within the West Coast Groundwater Basin.¹⁹ Groundwater beneath LAX is not used for municipal or agricultural purposes. Construction and operation of the proposed project would not require the use of groundwater and thus, would not deplete groundwater supplies. In addition, the project is the relocation of an existing use to another location within the airport boundaries. The project site is developed and paved. The project would introduce landscaping into the area and thus, provide a slight increase in permeable areas at the site. Implementation of the proposed project would not substantially

¹⁹ Draft EIR/EIS for the LAX Proposed Maser Plan Improvements, January 2001.

deplete groundwater supplies or interfere with groundwater recharge, and no mitigation measures would be required.

- c. **Substantially alter the existing drainage pattern of the site or area, including through the alteration of the course of a stream or river, in a manner which would result in substantial erosion or siltation on- or off-site?**

No Impact. Construction of the proposed project would occur on a site that serves aircraft and is currently developed with cargo buildings and related facilities. Demolition of these buildings and possible reconditioning or replacement of airfield paving would not alter the existing drainage pattern of the site or result in substantial erosion or siltation. Therefore, the project would not result in an impact regarding drainage and no mitigation measures would be required.

- d. **Substantially alter the existing drainage pattern of the site or area, including through the alteration of the course of a stream or river, or substantially increase the rate or amount of surface runoff in an manner which would result in flooding on- or off site?**

No Impact. The project site is developed and currently contains buildings and paving. There are no streams or rivers on the site. Project implementation would not involve drainage system improvements and would not result in significant changes to existing drainage patterns or increases in surface water runoff quantities. In addition, the project site is not located within close proximity to a stream or a river; thus, project implementation would not result in flooding on- or off-site. As such, project implementation would not substantially alter the existing drainage pattern of the site or area that would result in flooding on- or off-site and no mitigation measures would be required.

- e. **Create or contribute runoff water which would exceed the capacity of existing or planned stormwater drainage systems or provide substantial additional sources of polluted runoff?**

No Impact. The project site is developed and currently contains buildings and pavement. The proposed project, with the incorporation of landscaping, would likely result in a decrease in runoff due to an increase in permeable materials. Project implementation would not involve drainage system improvements and would not result in changes to existing drainage patterns or increases in surface water runoff quantities. Therefore, no impact to the capacity of existing or planned stormwater drainage systems or water quality would occur and no mitigation measures would be required.

f. Otherwise substantially degrade water quality?

No Impact. As discussed Response No. VIII.a., project construction activities would occur in accordance with the Los Angeles Building Code Sections 91.7000 through 91.7016, which requires necessary permits, plan checks, and inspections to reduce effects of sedimentation and erosion. Additionally, project construction would occur in accordance with applicable discharge requirements as set forth by the LARWQCB. As part of the proposed project, implementation of SUSMP would occur, which would minimize potential water quality impacts during project operation. As such, no impact to water quality would result from the construction and operation of the proposed project, and no mitigation measures would be required.

g. Place housing within a 100-year flood plain as mapped on federal Flood Hazard Boundary or Flood Insurance Rate Map or other flood hazard delineation map?

No Impact. The project site is not located within a 100-year flood hazard area mapped on the relevant FIRM map²⁰ and does not involve the construction of housing. Therefore, no impacts resulting from the placement of housing within a 100-year flood plain would occur and no mitigation measures would be required.

h. Place within a 100-year flood plain structures which would impede or redirect flood flows?

No Impact. As previously discussed in Response No. VIII.g, the proposed project site is not located within a 100-year flood hazard area. Therefore, no impacts resulting from the placement of structures within a 100-year flood plain would occur and no mitigation measures would be required.

i. Expose people or structures to a significant risk of loss, injury or death involving flooding, including flooding as a result of the failure of a levee or dam?

No Impact. As delineated on the City of Los Angeles Inundation and Tsunami Hazard Areas map,²¹ the project site is not within a boundary of an inundation area from a flood control basin. In addition to the flood control basins delineated on the City map, the project site is not located within the downstream influence of any levee or dam. Therefore, no impacts due to the

²⁰ City of Los Angeles Planning Department, Safety Element of the City of Los Angeles General Plan, Exhibit F, 100-Year & 500-Year Flood Plains In the City of Los Angeles, March 1994. [Flood plains shown on this map reflect the relevant FIRM maps.]

²¹ City of Los Angeles Planning Department, Safety Element of the City of Los Angeles General Plan, Exhibit G, Inundation & Tsunami Hazard Areas In the City of Los Angeles, March 1994.

exposure of people or structures to a risk of loss, injury, or death involving flooding as a result of the failure of a levee or dam would occur and no mitigation measures would be required.

j. Inundation by seiche, tsunami, or mudflow?

No Impact. The project site is located approximately one and one-quarter miles east of the Pacific Ocean. The project site is not delineated as a potential inundation or tsunami impacted area in the City of Los Angeles Inundation and Tsunami Hazard Areas map.²² Mudflows are not a risk as the project site is located on, and is surrounded by, level terrain and urban development. Therefore, no impacts resulting from inundation by seiche, tsunami, or mudflow are anticipated to occur and no mitigation measures would be required.

IX. LAND USE AND PLANNING. *Would the project:*

a. Physically divide an established community?

No Impact. The proposed project site is located on a developed airport in an urbanized area. The 15-acre project site is currently occupied by cargo facilities, including the B-4 Hanger and Air Freight Building 12. The remainder of the project site is paved and used for cargo activities that involve trucks, other ground support vehicles, and aircraft. The proposed project would relocate an existing use from one area of the airport to another. Therefore, the proposed project would not disrupt or divide the physical arrangement of an established community. No impacts resulting from disruption or division of the physical arrangement of an established community would occur and no mitigation measures would be required.

b. Conflict with applicable land use plan, policy or regulation of an agency with jurisdiction over the project (including but not limited to the general plan, specific plan, coastal program, or zoning ordinance) adopted for the purpose of avoiding or mitigating an environmental effect?

No Impact. The proposed FBO is an allowable use pursuant to the LAX Interim Plan and applicable zoning. Use of the site as proposed is also being recognized as part of on-going planning efforts associated with the proposed LAX Master Plan.

²² City of Los Angeles Planning Department, *Safety Element of the City of Los Angeles General Plan, Exhibit G, Inundation & Tsunami Hazard Areas In the City of Los Angeles, March 1994.*

c. Conflict with any applicable habitat conservation plan or natural community conservation plan?

No Impact. As previously discussed in Response No. IV.f, the Dunes Specific Plan Area, a designated Los Angeles County Significant Ecological Area, is located remote from the site at the far western portion of the airport. There is no adopted Habitat Conservation Plan, Natural Community Conservation Plan, or other approved habitat conservation plan or other natural community conservation plan that includes the proposed project site or immediate vicinity. The proposed project, therefore, would not conflict with any such plans and no mitigation measures would be required.

X. MINERAL RESOURCES. *Would the project:*

a. Result in the loss of availability of a known mineral resource that would be of value to the region and the residents of the state?

No Impact. The State Mining and Geology Board classifies mineral resource zones throughout the State. The project site is contained within a MRZ-3 zone, which represents areas with mineral deposits whose significance cannot be evaluated from available data.²³ The proposed site is located on a developed airport in an urbanized area. Although there are two oil fields in the area surrounding the project site, no known mineral resources exist on or underlying the project site. The Hyperion Oil Field lies approximately one-half mile west of the project site and the El Segundo Oil Field lies approximately one-third mile south of the project site. No other known mineral resources exist in the vicinity of the project site. Therefore, the proposed project would not result in the loss of availability of a known mineral resource that would be of value to the region and the residents of the State and no mitigation measures would be required.

b. Result in the loss of availability of a locally-important mineral resource recovery site delineated on a local general plan, specific plan, or other land use plan?

No Impact. The proposed project site is not within an area delineated on the City of Los Angeles Oil Field & Oil Drilling Areas map in the City of Los Angeles General Plan Safety Element.²⁴ Furthermore, as discussed in Response No. X.a above, the project site does not

²³ U.S. Department of Transportation Federal Aviation Administration and City of Los Angeles, *Draft Environmental Impact Statement/Environmental Impact Report, Los Angeles International Airport Proposed Master Plan Improvements, Section 4.17, January 2001.*

²⁴ City of Los Angeles Planning Department, *Safety Element of the City of Los Angeles General Plan, Exhibit E, Oil Field & Oil Drilling Areas In the City of Los Angeles, May 1994.*

contain any known mineral resources. Therefore, the proposed project would not result in the loss of availability of a locally-important mineral resource recovery site and no mitigation measures would be required.

XI. NOISE. *Would the project:*

- a. Exposure of persons to or generation of noise in level in excess of standards established in the local general plan or noise ordinance, or applicable standards of other agencies?**

Less than Significant Impact. The L.A. CEQA Thresholds Guide (Guidelines) has been developed as a tool for evaluation of potential project related impacts to streamline the City's permit and development process.²⁵ This guidance document provides a recommended analysis method for project impacts and thresholds of significance which take into consideration standards established in the local general plan and municipal code. As such, the methodology and significance thresholds provided in Chapter I, Noise, of the Guidelines has been used to evaluate potential noise impacts related to the project.

Construction-period noise impacts are discussed below in Section XI.d. Noise generated by on-site construction activities would have a less than significant impact on surrounding residential uses.

As discussed below in Section XV, Transportation/Circulation, the proposed project is not anticipated to generate any meaningful net new vehicle trips; therefore, there would be no increase in traffic related noise. Other sources of operational noise (e.g., aircraft, GSE, line maintenance, and parking lot activities) are discussed below in Section XI.C and would have a less than significant impact on community noise levels. As impacts would be less than significant, no mitigation measures are necessary.

- b. Exposure of people to or generation of excessive groundborne vibration or groundborne noise levels?**

Less than Significant Impact. The project would be constructed using typical construction techniques. As such, it is anticipated that the construction equipment to be used during project construction would not cause excessive groundborne noise or vibration. Post-construction on-site activities are limited to airport uses that would not generate excessive

²⁵ City of Los Angeles, "L.A. CEQA Thresholds Guide," May 1994.

groundborne noise or vibration since all airplanes and GSE are equipped with compressed air rubberized tires that act as vibration isolators. In addition, any engine run-ups associated with project-related aircraft would be off-site and limited to existing LAX designated engine run-up areas. As such, potential impacts associated with the project would be less than significant. No mitigation measures are required.

c. A substantial permanent increase in ambient noise levels in the project vicinity above levels existing without the project?

Less than Significant Impact. The noise environment within the vicinity of the project site is determined by a combination of noise from motor vehicle traffic on nearby roadways and from aircraft operations. The closest noise-sensitive uses are the residences located across Imperial Highway in El Segundo which are within the 65 Community Noise Equivalent Level (CNEL) contour for aircraft noise.²⁶ As indicated in the Traffic Technical Memorandum, which is contained in Appendix C, the project would only generate six to 18 net peak hour trips. This small increment in traffic associated with the project would not result in a measurable or significant change in traffic related noise levels.²⁷ Since the proposed project is not anticipated to generate substantial net new vehicle trips or change the local circulation pattern, the assessment of potential operational noise impacts focuses on aircraft related operations.

A portion of the project site is currently occupied by Airborne Express, a commercial shipping company. Airborne Express currently utilizes a portion of the B-4 Hangar and a portion of the ramp area for warehouse space. Airborne's current level of activity ranges from two to four flight operations (commercial) per day, including operations at night and use of GSE (e.g., mechanical loading equipment and towing equipment) and heavy-duty trucks (delivery trucks). In addition, LAWA intends to curtail non-scheduled passenger charter flights at the Imperial Terminal, which is located west of the project site. The proposed Mercury FBO or other FBO's located at LAX are expected to absorb these flights. The relocation of the non-scheduled passenger charter flights from Imperial to other FBOs would represent an easterly shift in the location of these flights along the southern airport boundary rather than an increase in general aviation activity levels at the airport. This easterly shift would move these operations further away from residences located directly south of LAX across Imperial Highway in El Segundo. A slight reduction in noise levels would likely occur at these residences.

For aircraft related noise a significant impact on ambient noise levels would normally occur if noise levels at a noise sensitive use attributable to airport operations exceed 65 dBA.

²⁶ Department of Airports Noise Management Bureau, *Second Quarter 2002 Noise Report, 2002.*

²⁷ *Traffic volumes would have to double for traffic related noise levels to increase by three dBA.*

CNEL and the project increases ambient noise levels by 1.5 dBA CNEL or greater.²⁸ For all other on-site operations (taxiing aircraft, GSE, line maintenance, and parking lot activities) a significant impact on ambient noise levels would normally occur if noise levels at a noise sensitive use attributable to on-site operations causes the ambient noise level measured at the property line of affected uses to increase by 3 dBA CNEL to or within the “normally unacceptable” or “clearly unacceptable” category, or any 5 dBA or greater noise increase.²⁹

As discussed in Attachment A, Project Description, based on general aviation projections for the year 2015, the proposed project would result in a slight increase in the level of aircraft activity compared with the existing level of activity at Mercury FBO and activity associated with non-scheduled charter flights at Imperial Terminal. LAWA determined the CNEL impact of the additional operations on communities surrounding LAX (26 existing noise monitoring stations) using the Integrated Noise Model (INM). This model was developed by the FAA and has been used extensively for noise analysis at commercial airports. In addition, comparisons of the Maximum Noise Levels (L_{max}) and the maximum Sound Exposure Levels (SELs) were also undertaken.

There were no significant changes in the CNEL, SEL, and L_{max} levels at any of the affected location points based on the projected increase in operations. There was a 0.1 dBA expected increase in the CNELs at four sites in El Segundo and Lennox. The projected SELs reflected a 0.1 dBA increase at 10 sites. The expected L_{max} values did not change at any of the sites. The projected 0.1 dBA CNEL increase is well below the 1.5 dBA threshold and, therefore, would result in a less than significant impact.

The Mercury FBO on-site operations would include aircraft ground taxi during ingress/egress on the aircraft parking ramp, GSE, maintenance activities, and parking lot activities. As discussed above, while these activities currently exist on site, these activities are further evaluated below.

The proposed project would result in increased aircraft ground taxi during ingress/egress on the aircraft parking ramp at the project site. The majority of these operations are corporate jets and to a much lesser extent commercial jets. Large commercial jets (e.g., A-300, DC-10, MD-11, B-767, and B-747) taxiing at a distance of approximately 100 feet have maximum noise levels (L_{max}) in the range of 92 to 96 dBA.³⁰ At a distance of 600 feet (distance to closest residential uses across Imperial Highway) the noise level would be approximately 77 to 81 dBA L_{max} . Barrier/structure attenuation related to nearby buildings and the raised portion of Imperial

²⁸ In addition, the FAA's Airport Environmental Handbook indicates that its threshold of significance is a 1.5 dBA CNEL increase in noise in any sensitive area located within the 65 dB CNEL contour.

²⁹ The “normally acceptable” range for single family dwelling units is 50-60 CNEL; “conditionally acceptable” is 55-70 CNEL; “normally unacceptable” is 70-75 CNEL; and “clearly unacceptable” is above 70 CNEL.

³⁰ HMMH, Anchorage International Airport, Noise Assessment Report, February 11, 2000.

Highway would create a bermed effect and would provide a minimum barrier insertion loss of 15 dBA. Therefore, the maximum noise level would be approximately 62 to 66 dBA and only one dBA above the existing ambient noise level of 65 dBA CNEL. All corporate aircraft are anticipated to be below this maximum predicted noise level. In addition, with the relocation of the non-scheduled passenger charter flights from Imperial Terminal, residences located directly south of LAX across Imperial Highway would be further away from this activity and would likely experience a slight reduction in noise levels.

GSE as part of the project would be similar to existing GSE used at the existing FBO and would have typical maximum noise levels from 75-85 dBA at 50 feet. These pieces of equipment would operate intermittently throughout the day. At a distance of 600 feet (distance to closest residential uses across Imperial Highway noise levels from GSE) would be approximately 64 L_{max} .³¹ As discussed above, existing site specific barrier/structure attenuation would provide an additional reduction in noise of 15 dBA. The predicted increase in ambient noise levels would be well below the current ambient noise levels and well below an increase of 3 dBA. Therefore, GSE noise impacts would be less than significant. No mitigation measures are required.

As discussed in Attachment A, Project Description, Mercury provides line maintenance and overnight checks for general aviation and scheduled airlines. Routine overnight maintenance, referred to as "A" checks, are scheduled functional inspections performed from a checklist. The activities include lubrication of moving parts, servicing of fluids, inspection of components, hoses, electrical items and aircraft structure. A ground power unit (GPU) is used during these checks. The noise level for the GPU is 80 dBA L_{eq} at 50 feet. At a distance of 600 feet (distance to closest residential uses across Imperial Highway) the noise level would be approximately 59 L_{eq} . As discussed above, site specific barrier/structure attenuation would provide an additional reduction in noise of 15 dBA.

Various sounds, including automobile movement, car alarms, car horns, door slams, and tire squeals, may occur at the surface parking area. The activation of car alarms, sounding of car horns, slamming of car doors, and tire squeals would occur periodically and may occasionally be audible. Noise from these sources, even though intermittent and short-term in nature, may be intermittently audible to nearby sensitive land uses. Automobile movement would result in the most continuous source of noise and would result in a noise level of approximately 50 dBA at a distance of 25 feet. The resultant noise levels at the closest residence would not be audible due to traffic noise along Imperial Highway. Therefore, noise levels associated with operation of the parking facilities would be less than significant. Mercury FBO on-site operations (i.e., aircraft ground taxi during ingress/egress on the aircraft parking ramp, GSE, maintenance activities, and

³¹ Based on a noise attenuation rate of approximately 6 dBA per doubling of distance.

parking lot activities) would each contribute to a combined noise level. As discussed above, these activities may result in maximum noise levels that are audible at the nearest residence. However, given that these sources of noise would typically be short-term and intermittent, the combined noise level would not significantly change the CNEL at residences in close proximity to the project site.

d. A substantial temporary or periodic increase in ambient noise levels in the project vicinity above levels existing without the project?

Less than Significant Impact. Construction noise was evaluated by determining the noise levels generated by outdoor construction activity and calculating the potential for exposure to noise-sensitive uses. A significant noise impact from construction would occur if the project would result in one or more of the following conditions:³²

- construction activities lasting more than one day would exceed existing ambient exterior noise levels by 10 dBA or more at a noise sensitive use;
- construction activities lasting more than 10 days in a three month period would exceed existing ambient exterior noise levels by 5 dBA or more at a noise sensitive use; or
- construction activities would exceed the ambient noise level by 5 dBA at a noise sensitive land use between the hours of 9:00 P.M. and 7:00 A.M. Monday through Friday, before 8:00 A.M. or after 6:00 P.M. on Saturday, or at anytime on Sunday.

Ambient noise levels at the noise-sensitive uses were determined from the Second Quarter 2002 Noise Report.³³ The closest noise-sensitive uses are the residences located across Imperial Highway which are within the 65 CNEL contour for aircraft noise. Construction noise levels were based on typical levels contained in the L.A. CEQA Thresholds Guide, as derived from USEPA documents. Distances between the noise-sensitive uses and the construction site were measured and construction noise levels at the sensitive uses were calculated based on standard noise-versus-distance relationships. Impacts were then calculated based on thresholds for exceedance of ambient noise levels.

Noise levels from outdoor construction indicate that the noisiest phases of construction are typically during grading and finishing, and that noise levels from equipment with mufflers is typically 86 L_{eq} at 50 feet from the noise source. Noise levels diminish at a rate of

³² *City of Los Angeles, L.A. CEQA Thresholds Guide, May 14, 1998.*

³³ *Department of Airports Noise Management Bureau, Second Quarter 2002 Noise Report, 2002.*

approximately 6 dBA per doubling of distance. Thus, a noise level of 86 dBA at a reference distance of 50 feet would be about 80 dBA at 100 feet, and 74 dBA at 200 feet. At a distance of 600 feet (distance to closest residential uses across Imperial Highway) would be approximately 65 L_{eq} . As discussed above, site specific and existing barrier/structure attenuation would provide an additional reduction in noise of 15 dBA. The predicted increase in ambient noise levels would be 65.1, or an increase of 0.1 dBA and, therefore, construction noise impacts would be less than significant. No mitigation measures are required.

- e. **For a project located within an airport land use plan or, where such a plan has not been adopted, within two miles of a public airport or public use airport, would the project expose people residing or working in the project area to excessive noise levels?**

No Impact. The proposed project would entail the consolidation and relocation of existing FBO operations within existing airport boundaries. No changes would be made to runway locations or configurations as part of the project. Over time, based on the projections for general aviation at LAX, there may be an increase in the number of general aviation operations. However, based on the slight increase in activity that would be experienced at the proposed facility, aircraft noise single event level (SEL) and community noise equivalent level (CNEL) contours would remain unchanged. As such, no impacts are anticipated and no mitigation would be required.

- f. **For a project within the vicinity of a private airstrip, would the project expose people residing or working in the project area to excessive noise levels?**

No Impact. The project site is not located within the vicinity of a private airstrip, but rather within a public airport. Those working or using the site would be exposed to noise levels normally expected for an airport terminal operation. See Response to Comment XI, e., above.

XII. POPULATION AND HOUSING. *Would the project:*

- a. **Induce substantial population growth in an area either directly (for example, by proposing new homes and businesses) or indirectly (for example, through extension of roads or other infrastructure)?**

No Impact. The proposed project would relocate and consolidate the Mercury Air Group FBO at Los Angeles International Airport. The level of aircraft activity and the number of employees would not substantially increase with implementation of the proposed project. With no meaningful increase in employment and no new homes and/or businesses proposed, direct or

indirect increases in population growth are not expected as a result of the project. Furthermore, the project site is located within a developed airport and no new roads or extensions of existing roads or other infrastructure are proposed. Therefore, the proposed project would not directly or indirectly induce population growth and no impacts would occur. No mitigation measures are required.

b. Displace substantial numbers of existing housing necessitating the construction of replacement housing elsewhere?

No Impact. There are no existing residential properties within the proposed project site. Implementation of the proposed project would not result in displacement of housing. No mitigation measures would be required.

c. Displace substantial numbers of people necessitating the construction of replacement housing elsewhere?

No Impact. While the project includes demolition of two existing buildings, the project would not affect housing or displace people thereby necessitating construction of replacement housing. Therefore, no impacts would occur and no mitigation measures would be required.

XIII. PUBLIC SERVICES. *Would the project result in substantial adverse physical impacts associated with the provision of new or physically altered governmental facilities, construction of which could cause significant environmental impacts, in order to maintain acceptable service ratios, response times or other performance objectives for any of the public services:*

a. Fire protection?

No Impact. The City of Los Angeles Fire Department provides fire protection services throughout Los Angeles International Airport, including the proposed project site. Fire Station No. 51, located at 10435 South Sepulveda Boulevard, is approximately one-half mile north of the proposed project site. Access to the project site would be kept clear and unobstructed at all times during construction in accordance with FAA, State Fire Marshal, and Los Angeles Fire Code regulations. Fire service requirements are generally based on the size of the building and relationships to other structures and property lines. The proposed project site is currently developed and the boundary of the proposed project would not extend beyond the current airport boundary. The proposed project would relocate and consolidate the Mercury Air Group FBO at LAX. Furthermore, the proposed project would upgrade on-site fire safety mechanisms to meet current fire safety code requirements. The proposed project would comply with all applicable

City, State, and federal codes and ordinances and architectural plans will be reviewed and approved by the City of Los Angeles Fire Department prior to project implementation. Therefore, the proposed project would not result in any substantial increase in demand for fire protection services which would result in the need for new or altered fire protection services. No significant impacts to or need for new or altered fire protection services is anticipated and no mitigation measures would be required.

b. Police protection?

No Impact. Both the Los Angeles World Airports Police Division (LAWAPD) and the City of Los Angeles Police Department LAX Detail (LAPD LAX Detail) provide police protection services to the airport, including the project site. The LAWAPD is located approximately one mile north of the project site and the LAPD LAX Detail station is located approximately 0.8 miles north of the project site. Demand for on-airport police protection services is typically determined by increases in aircraft activity and employees. Based on projections for general aviation activity at LAX, an increase in overall general aviation at LAX is assumed. The project may experience an increase of up to eight operations per day by 2015. Based on this increase at the project site and given that staffing levels and facility needs for police services at LAX are routinely addressed and accounted for in long-range plans, no impacts on airport police protection services is expected with implementation of the proposed project. Therefore, no mitigation measures would be required.

c. Schools?

No Impact. The proposed project would relocate and consolidate the Mercury Air Group FBO at Los Angeles International Airport. The number of employees serving FBO's at LAX would not increase with implementation of the proposed project. (The project is not expected to generate new employees, however, a worst-case scenario for the traffic analysis assumes a 25 percent increase in the number of employees.) Since the proposed project would not include residential development or generate a substantial number of new employees, no enrollment increases would occur with implementation of the proposed project. Therefore, no impacts to or the need for new school facilities would occur and no mitigation measures would be required.

d. Parks?

No Impact. The proposed project would relocate and consolidate the Mercury Air Group FBO at Los Angeles International Airport. The number of employees would not increase with implementation of the proposed project. (The project is not expected to generate new employees, however, a worst-case scenario for the traffic analysis assumes a 25 percent increase in the number of employees.) Since the proposed project would not include residential

development or generate a substantial number of new employees, additional demand for parks would not occur as a result of the proposed project. As such, no impacts to or the need for new parks would occur and no mitigation measures would be required.

e. Other governmental services (including roads)?

No Impact. The development of the Mercury Air Group FBO would not result in any substantial increase in demands on other governmental services. Thus the project would not increase the need for maintenance of such services, including roads. No impacts to other governmental services would occur and no mitigation measures would be required.

XIV. RECREATION.

a. Would the project increase the use of existing neighborhood and regional parks or other recreational facilities such that substantial physical deterioration of the facility would occur or be accelerated?

No Impact. The proposed project would relocate and consolidate the Mercury Air Group FBO at Los Angeles International Airport. The number of employees would not increase with implementation of the proposed project. (The project is not expected to generate new employees, however, a worst-case scenario for the traffic analysis assumes a 25 percent increase in the number of employees.) Since the proposed project would not include residential development or generate a substantial number of new employees, additional demand for parks or other recreational facilities is not anticipated. Therefore, the proposed project would not increase the use of existing parks or recreational facilities and no mitigation measures would be required.

b. Does the project include recreational facilities or require the construction or expansion of recreational facilities which might have an adverse physical effect on the environment?

No Impact. The proposed project would relocate and consolidate the Mercury Air Group FBO at Los Angeles International Airport. As discussed in Response No. XIV.a, the proposed project would not result in the need for new recreational facilities. Furthermore, the proposed project does not include recreational facilities or require the construction or expansion of recreational facilities. No impacts would occur and no mitigation measures would be required.

XV. TRANSPORTATION/CIRCULATION. *Would the project:*

- a. **Cause an increase in traffic which is substantial in relation to the existing traffic load and capacity of the street system (i.e., result in a substantial increase in either the number of vehicle trips, the volume to ratio capacity on roads, or congestion at intersections)?**

No Impact. A Traffic Technical Memorandum is provided in Appendix C. Table 3 on page B-36 summarizes the project trip generation and trip rates.

The trip generation rates used for the analysis are taken from the ITE Trip Generation Manual, 6th Edition. General Aviation Airport trip generation rates are based on the number of employees, however, the factor also accounts for passenger trips. The trip generation rate for the existing facility is 1.03 trips. Using this trip generation rate, which accounts for passengers and employees, the project would generate 45 P.M. peak hour trips. While no increase in employees is anticipated, for analysis purposes a 25 percent increase is assumed. Using this assumption, the project would generate 57 employee and passenger trips in the p.m. peak hour.

The Coastal Transportation Corridor Specific Plan articulates trip generation rates for airport-related land uses. Trip credit for demolition of the uses on the project site, which include Airborne Express, Aeroground, and the LAX Lost and Found buildings, all of which have all been active within the last two years, would result in the proposed project receiving credit for 39 existing afternoon peak hour trips. Accounting for this credit and based on current estimates of the Mercury FBO's trip generation, the project would generate six net P.M. peak hour trips. Based on a 25 percent increase in employees, the project would generate 18 net P.M. peak hour trips.

Based on the trip generation analysis, the project would not generate enough net trips to meet the City of Los Angeles Department of Transportation (LADOT) requirements of 43 peak hour trips for the preparation of a Traffic Impact Analysis. It should also be noted that the trips using the existing level of employment already occur today. These trips would relocate from the west side of the airport. The shift in trips from Imperial Terminal would not affect the traffic analysis. The project site would result in a reduction of trip length for Mercury FBO employees and these trips would pass through the same intersections that are currently used. Therefore, the project would not cause an increase in traffic which is substantial in relation to the existing traffic load and capacity of the street system and the project would not have a significant impact. No mitigation measures would be required.

Table 3

SUMMARY OF PROJECT TRIP GENERATION

Use	Type of Use	Size	PM Peak Hour
<u>Proposed Uses</u>			
Mercury FBO Facility	General Aviation Airport	44 to 55 employees ^a	45 to 57 ^a
<u>Existing Uses to be Removed</u>			
Airborne Express (B4 Hangar) ^b	Cargo Facility (partially occupies B4 Hangar)	12,400 sf	10
Aeroground (b4 Hangar) ^c	Cargo Facility (partially occupies B4 Hangar)	30,000 sf	24
LAX Lost and Found (Air Freight Building 12)	Storage	16,387 sf	5
Total Existing Trips			39
TOTAL NET TRIPS			6 to 18 ^c

^a Existing number of employees is 44. While this number is not expected to increase, for analysis purposes a 25 percent increase in employment is assumed. Therefore, the worst case analysis would be an increase to 55 employees. Trip generation factors for employment include associated passenger activity.

^b Aeroground facility was active within the past two years per LAWA Lease – LLA7742: June 2, 1998 to July 31, 2001.

^c Total net trips equal the projected trips minus the existing trips (i.e., $45 - 39 = 6$ and $57 - 39 = 18$). Two numbers are provided to reflect the same number of employees as well as a worst case analysis of a 25 percent increase in employment.

Notes:

sf = square feet

Trip Generation Rate from ITE Trip Generation Manual, 6th Edition:

General Aviation Airport: PM peak hour – 1.03 trips/employee

Cargo Facility: PM peak hour = 0.8 trips/1,000 sf

Storage: PM peak hour = 0.3 trips/1,000 sf

Source: Kaku, Associates, Inc., Traffic Technical Memorandum, February 2003 (see Appendix C)

b. Exceed, either individually or cumulatively, a level of service standard established by the county congestion management agency for designated roads or highways?

No Impact. As indicated above in XV.a and in the Traffic Technical Memorandum, which is contained in Appendix C, assuming a worst case analysis including a 25 percent increase in employees, the project would generate 18 net peak hour trips. The proposed project would not add 50 or more trips during the A.M. or P.M. weekday peak hours at any Congestion Management Plan (CMP) intersection, nor would the project add 150 or more trips during the A.M. or P.M. weekday peak hours at any CMP mainline freeway monitoring location. Thus, the project would not exceed any CMP thresholds. No impacts associated with implementation of the CMP would result, and no mitigation measures would be required.

c. Result in a change in air traffic patterns, including either an increase in traffic levels or a change in location that results in substantial safety risks?

No Impact. The project would relocate existing flights from the Mercury FBO facility on the west side of the airport to the project site on the south side of the airport. In addition, the project would shift non-scheduled charter flights from Imperial Terminal to the east to the project site. No changes would be made to runway locations and configurations as a result of the project. Based on projections, the proposed facility would experience a slight increase in activity due to an overall increase of general aviation activity at LAX. The project would not result in a change in air traffic patterns or an increase in traffic levels or change in location that would result in substantial safety risks. Therefore, no mitigation measures would be required.

d. Substantially increase hazards to a design feature (e.g., sharp curves or dangerous intersections) or incompatible uses (e.g., farm equipment)?

No Impact. The project would represent continued use of the site to serve aircraft with a change in focus from cargo to passengers. While access drives and on-site parking would be provided for clients and workers, these areas would be isolated from the apron and airfield. The project does not include any changes to design features on the existing roadways. The project would not alter or create any design features that would create a hazard on-site or in adjacent apron or airfield areas.

e. Result in inadequate emergency access?

No Impact. LAWA and tenants of LAX maintain Emergency Response and Evacuation Plans to minimize the potential for and the effects of an accident, should one occur. In addition, the project site is accessible from the public road to the south as well as from other areas of LAX. The project would not interfere with emergency access. The Mercury Air Group, as a tenant at LAX, would modify the existing Emergency Response and Evacuation Plan for the proposed site to ensure that emergency access is maintained. As such, construction and operation of the proposed project would not result in inadequate emergency access and no mitigation measures would be required.

f. Result in inadequate parking capacity?

No Impact. As indicated in Attachment A, Project Description, and shown on Figure 4, the project would provide approximately 280 parking spaces divided into four clusters along the southern portion of the project site. The easternmost area would contain 33 spaces for maintenance employee parking. To the west of that parking cluster would be a 90-space fenced, security parking area with card key access. A general FBO 90-space parking area would be

located to the west of the main entrance. The fourth area would be to the west of the proposed air center building and would contain 66 spaces for employee parking. The proposed parking would provide for the consolidation of Mercury parking that exists at the present Mercury site as well as Mercury employee parking at Imperial Terminal. In addition, the project would provide for the relocation of approximately 50 secure parking spaces primarily used for non-scheduled charter flights at the Imperial Terminal. The project would provide adequate parking for current and future uses and therefore, would not result in an impact to parking capacity. No mitigation measures would be required.

g. Conflict with adopted policies, plans, or programs supporting alternative transportation (e.g., bus turnouts, bicycle racks)?

No Impact. The project is the relocation and consolidation of an existing FBO facility at LAX. The project is contained entirely within airport property and off of public roadways. As such, the project would not conflict with policies, plans, or programs supporting alternative transportation.

XVI. UTILITIES. *Would the project:*

a. Exceed wastewater treatment requirements of the applicable Regional Water Quality Control Board?

No Impact. The City of Los Angeles Department of Public Works, Bureau of Sanitation, provides wastewater services for the site. The City of Los Angeles operates four wastewater treatment facilities that provide sewage treatment for most of the City's incorporated area and for several other cities and unincorporated areas in the Los Angeles region. Sanitary wastewater generated by activities at LAX, including the existing FBO, is treated at Hyperion Treatment Plant (HTP). HTP is located adjacent to the southwest boundary of LAX, approximately two miles southwest of the CTA. Currently, HTP has a design capacity of 600 million gallons per day (mgd). Average flows at HTP were 352 in April 2000, leaving an excess capacity of close to 248 mgd.³⁴ A collector sewer line is located to the west of the project site and runs parallel to Imperial Highway. Project implementation would relocate activities to another area within LAX but would not result in a substantial increase in wastewater flows from LAX. The project would make any necessary tie-ins to the existing facilities. Therefore, no impact with regard to wastewater treatment would occur and no mitigation measures would be required.

³⁴ Draft EIR/EIS for the LAX Proposed Master Plan Improvements, January 2001.

b. Require or result in the construction of new water or wastewater treatment facilities or expansion of existing facilities, the construction of which could cause significant environmental effects?

No Impact. As discussed in Response No. XVI.a., above, and e., below, project implementation would not result in a substantial increase in water demand and wastewater generation since the activity already exists within LAWA property. Existing water and wastewater facilities are adequate to serve the proposed project. As such, implementation of the project would not require or result in the construction of new water or wastewater treatment facilities or expansion of existing facilities. No impact to water or wastewater facilities would occur and therefore, no mitigation measures would be necessary.

c. Require or result in the construction of new stormwater drainage facilities or expansion of existing facilities, the construction of which could cause significant environmental effects?

No Impact. At LAX, stormwater is discharged to both County of Los Angeles and City of Los Angeles drainage and flood control structures. The existing drainage system at LAX consists of catch basins, subsurface storm drains and open channels, and outfalls. The project site is within the Argo Drain Subbasin. The project site is developed and paved and project implementation would not increase the amount of surface run off from the site. Therefore, the project would not result in the need to construct new stormwater drainage facilities or to expand existing facilities, the construction or expansion of which would cause environmental effects to occur.

d. Have sufficient water supplies available to serve the project from existing entitlements and resource, or are new or expanded entitlements needed?

No Impact. The City of Los Angeles Department of Water and Power (DWP) is the water purveyor for LAX. DWP is responsible for supplying, treating, and distributing water within the City. Current City of Los Angeles planning indicates that water supply will be sufficient to meet projected demands.³⁵ LAX is served by a 36-inch trunk line in Sepulveda Boulevard that distributes water to a combination of 12-inch and 16-inch transmission lines running along the airport perimeter. The project would relocate an existing FBO from one area within LAX to another area. Transmission lines are available at the project site. Project implementation would not result in an increase in water consumption. Since the transmission lines are in place and there would be no increase in water demand with the proposed project, there would be sufficient water infrastructure and supplies available to serve the project, and no

³⁵ *Ibid.*

new or expanded entitlements would be needed. Therefore, project implementation would not result in adverse impacts to water supplies and no mitigation measures would be required.

- e. **Result in a determination by the wastewater treatment provider which serves or may serve the project that it has adequate capacity to serve the project's projected demand in addition to the provider's existing commitments?**

No Impact. As discussed in Response Nos. XVI.a. and b., above, project implementation would not result in a substantial increase in wastewater generation since the activity already exists within LAWA property. Existing wastewater facilities are adequate to serve the proposed project. Therefore, no impact to wastewater facilities would occur and no mitigation measures would be necessary.

- f. **Be served by a landfill with sufficient permitted capacity to accommodate the project's solid waste disposal needs?**

No Impact. Solid waste management at the project site is conducted by both LAWA and private companies. Currently, solid waste generated at the project site is collected by Waste Management Inc. for disposal off-site. During project operation, solid waste from the site could be taken to one of several Class III landfills located within the Los Angeles County. Class III landfills accept all types of non-hazardous solid waste. The mid- to long-term solid waste disposal capacity availability in Los Angeles County is uncertain. Efforts are underway to address the disposal capacity issue in the region. For example, plans to enable the expansion of Sunshine Canyon landfill are underway. In addition, the County Sanitation Districts of Los Angeles County is seeking a 10-year extension of its operating permit for the Puente Hills Landfill. In light of landfill capacity issues throughout the state, in 1989 the state legislature enacted AB 939, which requires each city and county to divert 50 percent of their waste streams by the year 2000. LAWA developed a program to achieve waste diversion mandated by AB 939. In 1999, LAX achieved a diversion rate of 54 percent.³⁶ The proposed project is the relocation and consolidation of existing uses from other areas of the airport to one area within the airport boundary, with a slight increase in operations based on 2015 projections. The potential increase of eight operations a day would result in a negligible increase in solid waste disposal from passengers on those flights. Therefore, no impacts would occur and no mitigation measures would be required.

Construction of the proposed project would generate demolition debris. All demolition debris will be recycled or reused on-site to the extent possible, rather than disposed of at a landfill. For example, the B-4 Hangar is primarily steel and Air Freight Building 12 has a

³⁶ *Ibid.*

framework of steel. All demolished steel will be recycled. Asphalt and concrete will be recycled and reused to the extent feasible. In the event that demolition debris would be disposed of at regional landfills, inert waste, including asphalt, could be accepted at one of four following unclassified landfills within the Los Angeles County: Azusa Land Reclamation located in Azusa; Nu-Way Live Oak located in Irwindale; Peck Road Gravel Pit located in Monrovia; and Reliance Pit #2 located in Irwindale. Since unclassified landfills in the County do not generally have capacity issues, inert landfills serving the site would have sufficient capacity to accommodate project construction solid waste disposal needs and no impact would occur. Since the majority of the demolished material would be recycled and capacity exists at inert landfills for minor amounts of demolition debris that may need to be disposed of at landfills, no mitigation measures are required.

g. Comply with federal, state, and local statutes and regulations related to solid waste?

No Impact. The proposed project would operate in accordance with the City's Solid Waste Management Policy Plan and Framework Element of the General Plan, in addition to any applicable federal and State regulations associated with solid waste. Since the project would comply with federal, State, and local statutes and regulations related to solid waste, no impact would occur. No mitigation measures would be required.

XVII. MANDATORY FINDINGS OF SIGNIFICANCE.

a. Does the project have the potential to degrade the quality of the environment, substantially reduce the habitat of fish or wildlife species, cause a fish or wildlife population to drop below self-sustaining levels, threaten to eliminate a plant or animal community, reduce the number or restrict the range of a rare or endangered plant or animal or eliminate important examples of the major periods of California history or prehistory?

No Impact. The project is the relocation and consolidation of an existing fixed base operation at LAX from the western side of the airport to the southern side of the airport. The approximately 15-acre project site is currently occupied by two buildings, which would be demolished. The remainder of the site is primarily covered in impervious surfaces. The site does not support sensitive species or water bodies. Because of the long use of the site as part of LAX and high levels of aircraft and human activity, project implementation does not have the potential to substantially reduce the habitat of fish or wildlife species, cause a fish or wildlife population to drop below self-sustaining levels, threaten to eliminate a plant or animal community, or reduce the number or restrict the range of a rare or endangered plant or animal. In addition, as indicated in the responses to the checklist, the project would not degrade the

quality of the environment. No potential impacts were determined to occur from implementation of the project in any of the topical areas addressed above.

- b. Does the project have impacts which are individually limited, but cumulatively considerable? ("Cumulatively considerable" means that the incremental effects of an individual project are considerable when viewed in connection with the effects of past projects, the effects of other current projects, and the effects of probable future projects).**

Less Than Significant Impact. The proposed project would not generate impacts that are individually limited but cumulatively considerable. The proposed FBO is an allowable use pursuant to the LAX Interim Plan, which is currently in place. The proposed use is being recognized in on-going planning efforts at LAX, including the proposed LAX Master Plan. Based on the developed nature of the site and the fact that the project is the relocation and consolidation of a fixed base operation, the potential project-related impacts would be less than significant and sufficiently limited so as to preclude any substantial contribution to cumulative effects. Project implementation could result in an increase in operations at the project site by 2015 based on projections for general aviation activities at LAX. However, given the nature of the facility and the daily fluctuations in activity, no additional employees are expected to result from the project. Although the project is not expected to cause an increase in vehicular trips by employees and passengers over levels generated at the existing FBO facility and Imperial Terminal, additional trips that might be associated with forecasted growth in general aviation activity would be very limited and would not result in a significant cumulative impact on traffic. Additionally, the project operational air emissions, with the assumed increase in activity, would be below the SCAQMD significance thresholds. Furthermore, potential construction and operational noise impacts would be less than significant.

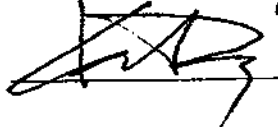

- c. Does the project have environmental effects which cause substantial adverse effects on human beings, either directly or indirectly?**

No Impact. Based on the documentation provided above, implementation of the proposed project would not cause environmental effects that cause direct or indirect substantial adverse effects on human beings.

Los Angeles World Airports

BOARD OF AIRPORT COMMISSIONERS

APPROVED BY: 	Meeting Date: 10-20-03
REVIEWED BY:  Richard M. Danisse, Deputy Executive Director	CAO Report <input checked="" type="checkbox"/> Completed <input type="checkbox"/> Pending <input type="checkbox"/> N/A
REVIEWED BY:  Paul L. Green, Chief Operating Officer	
CITY ATTORNEY: 	
EXECUTIVE DIRECTOR: 	Reviewed by: Budget <u>8/19/03</u> e-mail Environmental Mgt. <u>5/27/03</u> e-mail Procurement <u>8/21/03</u> e-mail

SUBJECT:

APPROVAL OF A 30-YEAR GROUND LEASE WITH MERCURY AIR GROUP, INC. FOR DEVELOPMENT OF A FIXED BASE OPERATION FACILITY AND APPROVAL OF BUILDING AND CONSTRUCTION PERIOD RENTAL RATES AT LOS ANGELES INTERNATIONAL AIRPORT

RECOMMENDATION:

Management RECOMMENDS that the Board of Airport Commissioners:

1. ADOPT the staff report.
2. CERTIFY that the initial Study/Negative Declaration was prepared in accordance to the requirements of the California Environmental Quality Act (CEQA) and the Los Angeles City CEQA Guidelines;
3. CERTIFY that the Final Negative Declaration was presented to the Board and that the Board reviewed and considered the information contained therein before considering whether to approve the project;
4. FIND that the Initial Study/Negative Declaration reflects the independent judgement and analysis of the Board and ADOPT the Negative Declaration.
5. APPROVE building rental rates and construction period rates as set forth in this report.
6. APPROVE a 30-year Lease between the City of Los Angeles and Mercury Air Group, Inc. that will generate approximately \$1,147,560 after the first year in

annual revenue to LAWA.

7. AUTHORIZE the Executive Director to execute the lease, after approval as to form and legality by the City Attorney and approval by Los Angeles City Council.

DISCUSSION:

1. Prior Related Actions

Mercury Air Group, Inc. (Mercury) has operated at Los Angeles International Airport (LAX) as a Fixed Base Operator (FBO) since 1979. Their operations include fuel sales, aircraft maintenance, hangar space rental, full service aircraft ground support, aircraft parking and tie down services, catering services, and weather reporting.

Terms of Previous Lease:

Demised Premises: 1.9284 acres of land
 75,000 square feet of paved aircraft ramp

Lease Term: January 1, 1994 through December 31, 1998

Rent: \$189,991 per year

Mercury had anticipated an earlier move to an alternate location, but a final decision was delayed due to the lack of potential sites that would suit its needs. For this reason, the lease went into and has remained in a holdover status. Since the previous lease expired, Mercury has been on a month-to-month holdover on the leasehold premises and has complied with the provisions of the original lease, including the payment of rent at current rates.

2. Current Action

Mercury's present location is situated in an area of LAX that is operationally constrained and does not provide for development or modernization of existing operations because of limited space. While Mercury leases approximately two acres directly from LAWA, Mercury also has use agreements with American Airlines and Continental Airlines for regular use of aircraft ramp areas that are adjacent to Mercury's leasehold area. Mercury also makes regular use of aircraft gates at the West Imperial Terminal complex. The combination of these non-adjoining areas results in approximately the same acreage that would be utilized under the proposed long-term lease.

In addition to the impacts created by other construction projects in the surrounding area, a suitable location for a replacement facility near its existing location is not possible. After working with LAWA to identify potential alternate sites, the proposed location, situated near the Northwest corner of Sepulveda Boulevard and Imperial Highway, was determined to be the best site.

Mercury proposes to develop approximately 15 acres for its FBO operation. Mercury will demolish and remove the B-4 hangar and Air Freight Building 12 (AF 12), both of which are currently located on the site. These improvements are well past their useful economic lives and will prepare the way for a more functional and efficient use of the site. Development costs total approximately \$10,000,000 and will include aircraft ramp areas, an FBO operations center consisting of two buildings, and vehicle parking

areas. Mercury will have the initial lease term to amortize the improvements it constructs after which ownership will revert to the City.

Terms of Proposed Lease:

Demised Premises: 15.3008 acres of land
 Lease Term: 30 years, commencing upon execution by LAWA after City Council approval
 Rent: \$1,147,560 per year

The proposed lease term is consistent with LAWA Leasing Policy approved by the Board in March 2001. In addition, Mercury has agreed to designate a fuel farm area to be located on the demised premises. The lease requires Mercury, at its sole expense, to relocate its current fuel farm (located at 6851 Imperial Highway) to this new location if deemed necessary by the City during the term of the lease.

Proposed Leasehold and Facility Rental Rates

The rental components are broken into two periods—one for construction period rent and one for the balance of the term.

The construction period rental for the demised premises will be more than one half of the current Board approved rate. The rate shall be in effect for the first six months of the lease.

Construction Period:

<u>Lease Component</u>	<u>Unit</u>	<u>Old Rate</u>	<u>New Rate</u>	<u>6 Mo. Rent</u>
Land	15.3008 Ac.	N/A	\$ 64,328/mo.	<u>\$385,968</u>
			Total Rent	\$385,968

The balance of the lease term, excepting for an interim use of office space, will consist of payments for land only as this is a redevelopment project covering the site.

Post Construction Period:

<u>Lease Component</u>	<u>Unit</u>	<u>Old Rate</u>	<u>New Rate</u>	<u>Annual Rent</u>
Land	15.3008 Ac.	\$75,000 Ac./Yr.	\$75,000 Ac./Yr.	\$1,147,560
Office Space	5,538 Sf.	N/A	\$ 6.00 Sf./Yr.	<u>\$ 33,228</u>
			Total Annual Rent	\$1,180,788

Space rental for the portion of AF 12 that Mercury will use shall commence at the beginning of the seventh month and continue until the space is vacated in preparation for demolition.

The land rental rate of \$75,000 per acre per year is based upon Board Resolution No. 20491 adopted on December 15, 1999. This rate is subject to readjustment on January 1, 2004. The office space rental rate of \$6.00 per square foot per year is consistent with rent charged for other comparable airport buildings at LAX.

Environmental

The attached Initial Study/Negative Declaration was prepared for the project pursuant to the requirements of the California Environmental Quality Act. The Initial Study concluded that the proposed project, if implemented, would not have a significant environmental impact and the adoption of a Negative Declaration would be appropriate.

The Notice of Intent to Adopt an Initial Study and a Proposed Negative Declaration for the project was published in the Los Angeles Times newspaper and posted at the office of the County Clerk. Copies were also mailed to concerned agencies and individuals and the Westchester and El Segundo public libraries for review. In accordance with CEQA Guidelines Section 15073, the 20-day comment period for the Draft Negative Declaration was from April 17, 2003 to May 7, 2003. One comment letter was received from the attorneys representing the City of El Segundo stating "no comment" on the proposed Negative Declaration. Their comment has been noted and the letter has been included in the Final Negative Declaration. This comment does not require revisions to the Negative Declaration.

FISCAL IMPACT STATEMENT:

Approval of this lease will generate approximately \$1,147,560 in annual revenue for a total of \$34,255,602 over the 30-year term of the lease, which represents an approximate increase of \$957,569 in annual revenue.

STANDARD PROVISIONS:

1. An Initial Study/Negative Declaration has been prepared for this project. The Initial Study was completed in compliance with the California Environmental Quality Act (CEQA) and the Los Angeles City CEQA Guidelines. The Final Negative Declaration was presented to the Board for review and consideration prior to the Board taking action on the proposed project. Pursuant to CEQA Guidelines Section 15074(c), the location and custodian of documents and materials for the Initial Study/Negative Declaration for this project is Los Angeles World Airports, Environmental Management Division, 7301 World Way West, Third Floor, Los Angeles, California 90045.
2. Mercury Air Group, Inc. will comply with the provisions of the Service Contract Worker Retention and/or Living Wage Ordinances.
3. This item is statutorily exempt from the provisions of the Minority/Women Business Enterprise Program.
4. Mercury Air Group, Inc. has an Affirmative Action Plan and will comply with the provisions of the Affirmative Action Program.
5. Mercury Air Group, Inc. has been assigned a Business Tax Registration Certificate Number.
6. Mercury Air Group, Inc. has submitted the Certification with Child Support Obligations and will comply with the provisions of the Child Support Ordinance.
7. Mercury Air Group, Inc. has approved insurance documents, in the terms and amounts required, on file with the City of Los Angeles.

8. The lease is not subject to the provisions of Charter Section 1022 (Use of Independent Contractor).
9. The Lessee has executed the lease and it has been approved as to form by the City Attorney.
10. The action taken by the Board of Airport Commissioners will become final pursuant to the Los Angeles City Charter, Section 606.
11. Mercury Air Group has submitted the Contractor Responsibility Program Pledge of Compliance and will comply with the provisions of Contractor Responsibility Program.

NEWS RELEASE

LAX OPENS NEW PARKING STRUCTURE ACROSS TERMINAL 6

7/7/00

**-New parking structure offers more than 1,000
slots within Central Terminal Area-**

**CONTACT: Gail Gaddi
(310) 646-5260**

(LOS ANGELES - July 7, 2000) Finding a parking space for the 60,000 people who daily drive to the Central Terminal Area (CTA) of Los Angeles International Airport became easier today with the opening of a new parking structure with 1,000 additional spaces for short term parking.

The \$18-million structure, adjacent to Terminal 6, was completed two months ahead of schedule, just in time for the peak summer travel season. The four-level parking structure will provide 953 parking spaces - including 20 spaces for vehicles with disabled permits and 20 spaces for electric vehicles (EV). There will also be 115 metered parking spaces in the adjacent surface Parking Lot 6. This increases the total number of parking spaces within the CTA to more than 9,400. This new parking structure replaces an old structure that was demolished because of seismic concerns.

"As Passenger demand continues to grow at LAX, we strive to meet our passengers' needs. This project demonstrates our commitment to provide the best service possible to the traveling public," said Lydia H. Kennard, Los Angeles World Airports Executive Director.

Kennard added that one of the features of a proposed Master Plan to modernize LAX will be a six-level parking structure that will provide an additional 12,000 spaces and be located near a new western terminal.

Parking rates are the same as the other parking structures within the CTA. The price will be \$3 for the first two hours and \$1 for each additional hour, with a maximum of \$16 for 24 hours. Metered parking will be 25 cents for 15 minutes with a 2-hour maximum.

The first level of Parking Structure 6 will be restricted to a 2-hour maximum time limit for short term parking. Parking staff will monitor vehicles and give citations to vehicles that are parked longer than two hours.

Parking Structure 6 was designed by Walker Parking Consultants and constructed by S.J. Amoroso Construction Co., Inc. Construction management and oversight were provided by CMTS Inc., LAWA Engineering and Inspection, Public Works Inspection and General Services Standards Division.

Particularly during the busy summer vacation months, passengers are encouraged to use the approximately 11,000 low cost parking stalls available in Remote Parking Lots B and C, which are located outside of the CTA. Remote Parking Lots B at 96th Street and Sepulveda Boulevard and C at 111th Street and La Cienega Boulevard provide free, frequent shuttle service to and from the terminals.

LAX Construction - Project Status Report

JULY 2000

Priority CONSTRUCTION

Project Name: **CENTURY CARGO COMPLEX - CARGO BUILDING A**
 Project File No.: 97014
 Description: This project will provide for the construction of a 145,000 s.f. Cargo building in the Century Cargo Complex.
 Project Engineer: Van Thompson
 Total Project Cost: \$17,310,000
 Architect/Engineer: HOK
 Other Consultant (s): Tishman Construction
 General Contractor: M.A. Mortenson
 Construction Start Date: September 1999
 Estimated Construction Completion Date: September 2000
 Construction Contract Amount: \$11,987,000
 Approved Change Order(s): \$344,846
 Priority: Construction
 Comments: The project is approximately 76% complete.

Project Name: **SOUTHSIDE TAXIWAYS WG, WF, & T**
 Project File No.: 91014
 Description: This project will construct three high-speed taxiways on the South Airfield.
 Project Engineer: Mark Vicelja
 Total Project Cost: \$35,529,000
 Architect/Engineer: HNTB
 Other Consultant (s): Carter Burgess
 General Contractor: Kiewit Pacific Co.
 Construction Start Date: May 1999
 Estimated Construction Completion Date: March 2000
 Construction Contract Amount: \$24,258,426
 Approved Change Order(s): \$909,484
 Priority: Construction
 Comments: Construction is complete. Administrative contract close-out is in progress.

Project Name: **PARKING STRUCTURE 6**
 Project File No.: 91011
 Description: This project will construct a 4-Level, 953-car parking structure across from Terminal 6 at LAX.
 Project Engineer: Marlene Dupras
 Total Project Cost: \$18,631,000
 Architect/Engineer: Walker Parking Consultants
 Other Consultant(s): CMTS
 General Contractor: S.J. Amoroso
 Construction Start Date: July 1999
 Estimated Construction Completion Date: July 2000
 Construction Contract Amount: \$11,764,000
 Approved Change Order(s): \$1,874,735
 Priority: Construction
 Comments: The project is complete. Administrative contract close-out is in progress.

Project Name: **TBIT MEZZANINE ADDITIONAL SEATING**
 Project File No.: 98008
 Description: This project will add additional seating on the Food Court mezzanine level.
 Project Engineer: Jay Vaswani
 Total Project Cost: \$118,000
 Architect/Engineer: Leo A. Daly
 Other Consultant (s):
 General Contractor:
 Construction Start Date: December 1999
 Estimated Construction Completion Date: August 2000
 Construction Contract Amount: \$87,123
 Approved Change Order(s):
 Priority: Construction
 Comments: Samples were submitted and approved. Fabrication has commenced.

Los Angeles World Airports
 RESOLUTION NO. 20353

WHEREAS, on recommendation of Management, there was presented for approval, rejection of bids and authorization to re-advertise for bids for the project entitled "Parking Structure 6" at Los Angeles International Airport; and

WHEREAS, this project consists of construction of a new parking structure consisting of four levels and providing 373,700 square feet of gross floor space and 953 parking spaces. It will serve Terminal 6 and also connect to the existing vehicular bridge to Parking Structure 5. This structure will replace the already demolished parking structure at 551 World Way; and

WHEREAS, Resolution No. 20071 approved the Final Plans and Specifications for this project and authorized the Executive Director to advertise for bids. Bids received on March 24, 1998 are as follows:

CONTRACTOR	BASE BID	ALTERNATE NO. 1	ALTERNATE NO. 2	ALTERNATE NO. 3
SSC Construction	\$ 9,591,028	\$ 0	\$250,000	\$ 610,000
H.A. Lewis, Inc.	\$10,619,000	\$164,000	\$360,000	\$ 360,000
EMMA Corp.	\$11,300,000	\$200,000	\$250,000	\$ 360,000
Morse Diesel	\$11,304,500	\$ 15,000	\$ 30,000	\$ 45,000
PARR Contracting	\$11,610,000	\$250,000	\$700,000	\$1,600,000
SJ Amoroso Const.	\$11,660,000	\$225,000	\$325,000	\$ 425,000
Ray Wilson Co.	\$11,728,139	\$ 88,000	\$120,000	\$ 220,000

The two low bidders, SSC Construction and H.A. Lewis, Inc., have requested to be released from their bid in accordance with Sections 5100 of the California Public Contract Code. The Engineering Bureau and the City Attorney's Office have reviewed the documentation and determined that clerical errors (all costs were not included) were made by SSC Construction and H.A. Lewis, Inc. Since there is a significant difference between the lowest bid with errors corrected (almost \$1,000,000) and the third bidder, it is recommended that all bids be rejected and the project be re-advertised for bids; and

WHEREAS, this action, as a continuing administrative activity, is exempt from the requirements of the California Environmental Quality Act as provided by Article III, Section 2.f of the Los Angeles City CEQA Guidelines; and

WHEREAS, actions taken on this item by the Board of Airport Commissioners will become final pursuant to the provisions of the Los Angeles City Charter Section 32.3;

NOW, THEREFORE, BE IT RESOLVED that the Board of Airport Commissioners determined that this action is exempt from CEQA requirements, adopted the Staff Report, rejected all bids and authorized the Executive Director to re-advertise for bids for the Parking Structure 6 Project.

o0o

I hereby certify that the above is a true and correct copy of Resolution No. 20353 adopted by the Board of Airport Commissioners at a special meeting held Friday, August 7, 1998.

BOARD OF AIRPORT COMMISSIONERS REPORT

TO: The Board of Airport Commissioners	DATE OF BOAC MEETING May 19, 1998	DATE REPORT WRITTEN May 12, 1998
--	---	--

REFERENCE:
 PARKING STRUCTURE 6 - LOS ANGELES INTERNATIONAL AIRPORT
 FILE No. 91011

SUBJECT:
 AWARD OF CONTRACT TO EMMA CORPORATION FOR THE PROJECT ENTITLED "PARKING STRUCTURE 6" AT LOS ANGELES INTERNATIONAL AIRPORT.

SUMMARY:
 By Resolution No. 20071 dated December 16, 1997, the Board of Airport Commissioners approved the Final Plans and Specification for this project and authorized the Executive Director to advertise for bids. The design consultant's construction cost estimate for this project is \$11,623,500. Bids received on March 24, 1998, are as follows:

Contractor	Base Bid	Alternate #1	Alternate #2	Alternate #3
SSC Construction	\$ 9,591,028	\$ 0	\$250,000	\$ 610,000
H.A. Lewis, Inc.	\$10,619,000	\$164,000	\$360,000	\$ 360,000
EMMA Corp.	\$11,300,000	\$200,000	\$250,000	\$ 360,000
Morse Diesel	\$11,304,500	\$ 15,000	\$ 30,000	\$ 45,000
PARR Contracting	\$11,610,000	\$250,000	\$700,000	\$ 1,600,000
SJ Amoroso, Const.	\$11,660,000	\$225,000	\$325,000	\$ 425,000
Ray Wilson Co.	\$11,728,139	\$ 88,000	\$120,000	\$ 220,000

Of two low bidders, SSC Construction and H.A. Lewis, Inc., have requested to be released from their bid in accordance with Sections 5100 of the California Public Contract Code. Engineering and the City Attorney have reviewed the documentation and determined that clerical errors were made by SSC Construction and H.A. Lewis Incorporated. Release from their bids is recommended.

The level of participation established for this contract was 20% combined MBE/WBE. The Bureau of Contract Services confirms that EMMA Corporation, based on the documentation submitted, has made a good faith effort to outreach to MBE/WBE/OBE subcontractors for participation on this project. EMMA Corporation proposes a combined MBE/WBE participation of 17% and OBE participation of 83%.

COMMENDATION:
 In lieu of a report requesting that the Board of Airport Commissioners DECLARE that SSC Construction and H.A. Lewis, Inc., made clerical errors, RECOMMEND release of SSC Construction and H.A. Lewis, Inc., from their bids, RECOMMEND Award of Contract, based on the Base Bid to EMMA Corporation for the project entitled "Parking Structure 6 at Los Angeles International Airport" and appropriation of funds.

REVIEWED BY CITY ATTORNEY

EXECUTIVE DIRECTOR

DISCUSSION AND FINDINGS:

This project consists of construction a new parking structure, consisting of four (4) levels and providing 373,700 square feet of gross floor space and 953 parking spaces. It will serve Terminal 6 and also connect to the existing vehicular bridge to Parking Structure 5. This structure will replace the already demolished parking structure at 551 World Way.

The two low bidders, SSC Construction and H.A. Lewis, Incorporated, have requested to be released from their bid in accordance with Sections 5100 of the California Public Contract Code. Engineering and the City Attorney have reviewed the documentation and determined that clerical errors were made by SSC Construction and H.A. Lewis Incorporated. Release from their bids is recommended.

Walker Parking Consultants, LAWA's design consultants, recommends the construction of this project using the Base Bid duration of 14 months. LAWA staff has conducted an investigation into the experience, references, and financial statement submitted by EMMA Corporation, and has determined that the bidder is responsive and responsible. Therefore, award of the contract and allocation of funds are recommended.

The estimated cost of this project is as follows:

Construction Cost (Base Bid)	\$ 11,300,000.00
Contract Contingencies (20%)	\$ 2,260,000.00
DO to Dept. of Public Works for Inspection	\$ 635,000.00
DO to Dept. of General Services for Testing	\$ 275,000.00
DO to Cultural Affairs Dept. for Art Development Fee	\$ 112,900.00
	<hr/>
TOTAL ESTIMATED CONSTRUCTION COSTS	\$ 14,582,900.00

ISCAL IMPACT STATEMENT:

This is an approved 1995 Bond Construction Fund project, and Bond funds are available. It is, therefore, requested that the Board authorize the appropriation of \$14,582,900 from the appropriated Balance of the 1995 LAX Series D Bond Construction Fund to Work Order No. 9510.

STANDARD PROVISIONS:

The level of participation established for this contract was 20% combined MBE/WBE. The Bureau of Contract Services confirms that EMMA Corporation, based on documents submitted, has made a good faith effort to outreach to MBE/WBE/OBE subcontractors for participation on this project.

This award of contract is a normal follow-up activity, and accordingly, this activity is exempt from the requirements of CEQA as provided by Article III, Section 2.1 of the Los Angeles City CEQA Guidelines.

Action taken on this item by the Board of Airports Commissioners will become final pursuant to the provisions of the Los Angeles City Charter Section 32.3.

EMMA Corporation has an approved Affirmative Action Plan on file with the City of Los Angeles.

Management RECOMMENDS that the Board DETERMINE that this action is exempt from CEQA requirements, REQUEST that the Board DECLARE that SSC Construction and H.A. LEWIS, Inc., made clerical errors, RECOMMENDS release of SSC Construction and H.A. Lewis, Inc., from their bond, RECOMMEND Award of Contract to EMMA Corporation, and FURTHER REQUEST APPROPRIATION of \$14,582,900.00 from the Unappropriated Balance of the 1995 Series D Bond Construction Fund to Work Order No. 9510.

**PARKING STRUCTURE 6
LOS ANGELES INTERNATIONAL AIRPORT
FILE NO. 91011**

SUBJECT

AWARD OF CONTRACT TO WALKER PARKING CONSULTANTS/ENGINEERS, INC., COVERING CONSULTANT SERVICES FOR THE PROJECT ENTITLED "PARKING STRUCTURE 6" AT LOS ANGELES INTERNATIONAL AIRPORT.

SUMMARY Walker Parking Consultants/Engineers, Inc. is the Engineer of Record for the project entitled "Parking Structure 6" at Los Angeles International Airport. The contract documents were substantially completed in 1993, but construction of the project was delayed due to budgetary reasons. Walker's original contract has expired. This continuation contract will provide services to update and redesign the plans and specifications to meet new code requirements. This contract will also provide construction administration services and record drawings.

The proposed fee for the Consultant Services is as follows:

Basic Services	\$ 400,000.00
Extra Services	\$ 80,000.00
TOTALS CONTRACT	\$ 480,000.00

The Extra Services may include, but not be limited to, additional engineering, geotechnical, survey, printing, and construction scheduling services. All Extra Services, if needed, will require prior approval of the Executive Director.

RECOMMENDATION

Adoption of a report requesting that the Board of Airport Commissioners award a contract to Walker Parking Consultants/Engineers, Inc., for continuation of Consultant Services for the project entitled Parking Structure 6 at Los Angeles International Airport.

VIEWED BY CITY ATTORNEY

EXECUTIVE DIRECTOR

DISCUSSION AND FINDINGS

This item requests authorization for the Executive Director to enter into a contract with Walker Parking Consultants/Engineers, Inc. for the of Engineering Services for the project entitled Parking Structure 6 at Los Angeles International Airport.

This project will consist of a new parking structure consisting of four levels and providing 373,700 square feet of gross floor space and 953 parking spaces. It will serve Terminal 6 and also connect to the existing vehicular bridge to Parking Structure 5. This structure will replace the already demolished parking structure at 551 World Way.

This project was originally scheduled for construction in 1994 but was delayed due to budgetary concerns and further evaluation of parking capacity needs. Subsequently, the Facilities Planning Bureau has studied the parking needs in the Parking Structure 6 location and has determined that the structure is needed to meet current and future demand, and that the construction is advantageous from a financial perspective.

Because of the delay and the code changes resulting from the Northridge earthquake, the plans will require substantial structural upgrades. In addition, the Consultant will reevaluate the exit layout relative to use of credit cards, as well as make revisions required in connection with other code changes. The Consultant will provide construction administration services, as well as record drawings.

It is in the City's best interest to use Walker Parking Consultants/Engineers, Inc. for completion of final plans, construction administration services and the preparation of record drawings for the following reasons:

- 1) Walker Parking Consultants/Engineers, Inc. has particular and specific knowledge of the contract documents, having prepared the original studies, calculations, plans and specifications.
- 2) There are significant cost savings in having Walker Parking Consultants/Engineers, Inc. utilize the knowledge they have already gained in the preparation of the original contract documents.
- 3) Because of the impending construction of the improvements, time is of the essence. Walker Parking Consultants/Engineers, Inc. is immediately available to complete the contract documents and provide construction administrative services.

The proposed fee for the Consultant Services is as follows:

	Total
Basic Services	\$ 400,000.00
Extra Services	<u>\$ 80,000.00</u>
TOTAL CONTRACT	\$ 480,000.00
 Miscellaneous Project Costs	 \$ 75,000.00

In addition to the above additional contract funds, appropriation of \$75,000 for printing costs, plan check and miscellaneous fees is also requested.

STANDARD PROVISIONS

- 1. Walker Parking Consultants/Engineers, Inc. has an approved Affirmative Action Plan on file with the City of Los Angeles.

2. Walker Parking Consultants/Engineers, Inc. will continue to maintain or exceed the original Contract goals of 15% MBE and 5% WBE participation for this contract.
3. Walker has executed the Contract and the City Attorney has approved it as to form.
4. This project is exempt from the requirements of the California Environmental Quality Act as provided by Article VII, Class 2 (2) of the Los Angeles City CEQA Guidelines.
5. Actions taken on this item by the Board of Airport Commissioners will become final pursuant to the provisions of the Los Angeles City Charter, Section 32.3.

Management RECOMMENDS that the Board DETERMINE that this action is exempt from CEQA requirements, RECOMMENDS Award of Contract to Walker Parking Consultants/Engineers, Inc., REQUESTS AUTHORIZATION for the Executive Director to execute the contract with Walker Parking Consultants/Engineers, Inc., and FURTHER REQUESTS APPROPRIATION of \$362,000 from the Unappropriated Balance of the Airport Revenue Fund to the Unallocated Balance of the Capital Improvements Account, and then ALLOCATE \$362,000 from the Unallocated Balance to Work Order No. P674.

RESOLUTION NO. 19700

WHEREAS, on recommendation of Management, there was presented for approval, Award of a Contract to Walker Parking Consultants/Engineers, Inc. covering consultant services for the project entitled, "Parking Structure 6" at Los Angeles International Airport; and

WHEREAS, this project will consist of a new parking structure consisting of four levels and providing 393,700 square feet of gross floor space and 953 parking spaces. It will serve Terminal 6 and also connect to the existing vehicular bridge to Parking Structure 5. This structure will replace the already demolished parking structure at 551 World Way; and

WHEREAS, this project was originally scheduled for construction in 1994 but was delayed due to budgetary concerns and further evaluation of parking capacity needs. Subsequently, the Facilities Planning Bureau has studied the parking needs in the Parking Structure 6 location and has determined that the structure is needed to meet current and future demand, and that the construction is advantageous from a financial perspective; and

WHEREAS, because of the delay and the code changes resulting from the Northridge earthquake, the plans will require substantial structural upgrades. In addition, the Consultant will re-evaluate the exit layout relative to use of credit cards, we will as make revisions required in connection with other code changes. The Consultant will provide construction administration services, as well as record drawings; and

WHEREAS, it is the City's best interest to use Walker Parking Consultants/Engineers, Inc. for completion of final plans, construction administration services and the preparation of record drawings for the following reasons:

- 1) Walker Parking Consultants/Engineers, Inc. has particular and specific knowledge of the contract documents, having prepared the original studies, calculations, plans and specifications.
- 2) There are significant cost savings in having Walker Parking Consultants/Engineers, Inc. utilize the knowledge they have already gained in the preparation of the original contract documents.
- 3) Because of the impending construction of the improvements, time is of the essence. Walker Parking Consultants/Engineers, Inc. is immediately available to complete the contract documents and provide construction administrative services; and

WHEREAS, the proposed fee for the Consultant Services is as follows:

Basic Services	\$400,000
Extra Services	<u>\$ 80,000</u>
Total Contract	\$480,000
Miscellaneous Project Costs	\$ 75,000; and

WHEREAS, in addition to the above additional contract funds, appropriation of \$75,000 for printing costs, plan check and miscellaneous fees is also requested; and

WHEREAS, Walker Parking Consultants/Engineers, Inc. has an approved Affirmative Action Plan on file with the City of Los Angeles; and

WHEREAS, Walker Parking Consultants/Engineers, Inc. will continue to maintain or exceed the original Contract goals of 15% MBE and 5% WBE participation for this Contract; and

WHEREAS, Walker has executed the Contract and the City Attorney has approved it as to form; and

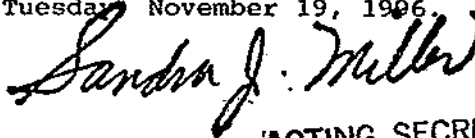

WHEREAS, this project is exempt from the requirements of the California Environmental Quality Act as provided by ~~Article 22, Section 2.2~~ of the Los Angeles City CEQA Guidelines; and

WHEREAS, this Contract is subject to approval of the City Council pursuant to Charter Section 390;

NOW, THEREFORE, BE IT RESOLVED that the Board of Airport Commissioners determined that this action is exempt from CEQA requirements, adopted the Staff Report, approved Award of a Contract to Walker Parking Consultants/Engineers, Inc. for continuation of consultant services for the project entitled, "Parking Structure 6" at Los Angeles International Airport, authorized the Executive Director to execute the Contract, and further approved Appropriation of \$362,000 from the Unappropriated Balance of the Airport Revenue Fund, to the Unallocated Balance of the Capital Improvements Account, and then Allocate \$362,000 from the Unallocated Balance to Work Order No. O.P674.

oOo

I hereby certify that the foregoing is a true and correct copy of Resolution No. 19700 adopted by the Board of Airport Commissioners at a regular meeting held Tuesday, November 19, 1996.

ACTING SECRETARY

Elaine E. Staniec - Secretary
BOARD OF AIRPORT COMMISSIONERS

CITY OF LOS ANGELES • DEPARTMENT OF AIRPORTS

DATE: March 15, 1996
TO: John J. Driscoll
FROM: John L. Graham *JL Graham*
SUBJECT: Rebuilding of Parking Structure 6

In response to your request to examine the necessity of rebuilding Parking Structure 6, which was demolished in 1991, we have determined that the structure is needed to meet current and future demand for parking at that location, and that the construction is advantageous from a financial perspective. We recommend proceeding immediately with an update of the plans and specifications so that the construction can begin as soon as possible.

Background

The previous Parking Structure 6 was demolished in 1991 because it did not meet current seismic regulations. A contract was awarded to Walker Parking Consultants/Engineers for design of a replacement structure. The plans and specifications were completed and checked by the Department of Building and Safety; however, the design will have to be updated and rechecked to conform with changes in the building code resulting from the Northridge earthquake.

The project consists of 393,700 square feet over four levels and provides 953 parking spaces. The structure will connect with the existing pedestrian bridge to Terminal 6 and the existing vehicular bridge to Parking Structure 5. It will provide parking primarily for Terminals 5 and 6. Total project cost in 1993 was estimated at \$10,630,000.

Distribution of Parking Demand in the CTA

It is difficult to closely match parking lots and structures in the CTA with specific terminal buildings because of the interconnections between some structures. However, it is useful to roughly tie the two together to gain insight into the relationship between passengers in a terminal and vehicle counts in and out of the structures. After an analysis of extensive data on passenger volumes and parking tickets issued and collected for all of the terminals and parking structures in the CTA, it appears that Parking Structure 5 and Lot 6 have an average number of vehicles entering and exiting in relation to the number of passengers for those terminals, and Parking Structure 7 has a low number of vehicles in relation to passengers. (Structure 7 usage is important to analyzing the need for a replacement structure in Lot 6 because United Airlines, currently in Terminals 7 and 8, is expanding into Terminal 6.) In Structure 5 and Lot 6, the majority of parking tickets are issued at 5 and collected at 6. It should be kept in mind that this comparison is very rough, and is affected by the number of parking spaces available and the length of time vehicles are parked rather than simply usage of the structures. In addition, some metered lots are highly utilized and are not included in these figures.

The number of passengers in relation to the number of available parking spaces in corresponding structures is shown in Figure 1. Ratios of available spaces to passengers are given in Table 1. Note that Structures 5 and 7 have average numbers of available spaces, and that Lot 6, of

SEARCHED
SERIALIZED
INDEXED

SAL00015

course, has a low number of available spaces. (Note: Calculations are based on total number of passengers rather than origin/destination passengers for each terminal.)

According to Parking Services, Parking Structure 7 is filled almost constantly on a daily basis. This information, combined with the generally low number of tickets issued and collected in relation to passengers; indicates that there may be insufficient parking for Terminal 7, even though Parking Structure 7 has an average number of spaces available in relation to volume of passengers. Analysis of the data indicates that there has been an increase in usage over time, except from 1994 to 1995, when retrofitting work was being performed. (However, revenues increased even from 1994 to 1995.) For Structure 5 and Lot 6, there has been a decline in parking tickets issued and collected from 1992 to 1995 (presumably attributable to the sluggish economy, which affected passenger traffic and other structures in the CTA). However, there still has been a slight increase in revenue for Structure 5 and Lot 6 from 1993 to 1995.

Regarding peak hour measurements, Leigh Fisher Associates calculated peak accumulation as part of their work for the LAX Master Plan (Table 2). The data indicates that the demand approached or exceeded the capacity of certain structures in the CTA. In particular, Structures 1, 3, 4, 5, and 7 were at full capacity during peak hours. Structures 4 and 5 were closed for several hours of the day. (Note: Perhaps the relatively low usage of Lot 6 during peak periods occurs because of the lack of access from the upper/departure level roadway).

Also as part of the Master Plan, Barton-Aschman Associates notes that the original CTA second level roadway project called for Parking Structure 6 to provide parking for Terminals 5 and 6. With the demolition of the structure, parking for Terminals 6, 7 and 8 is provided only in Structure 7, which is not accessible from the upper level of World Way South. Thus a motorist driving eastbound on upper level World Way South must use the airport return and travel through the critical upper level World Way North-Sky Way intersection to access parking via East Way. Once the United terminal expansion program is completed, there will likely be a significant negative impact to the World Way North-Sky Way intersection. In addition, there is likely to be insufficient convenient parking for the affected terminals (6, 7 and 8). Barton-Aschman recommends, therefore, that a new Parking Structure 6, with access from the upper level of World Way South or perhaps northbound East Way; be constructed.

Finally, the Master Plan public parking forecasts project a growth in CTA parking space requirements from 8,500 spaces in 1994 to 10,500 spaces in 2000 (and 16,000 in 2015). The best available site for developing additional CTA parking is on Lot 6, especially considering the need for more parking in that area of the CTA.

Revenues and Cost Recovery

Revenues for CTA parking structure groupings for 1992 to 1995 are attached. Structure 7 had revenues of approximately \$6.4 million in 1995; Structure 5 and Lot 6 combined had revenues of about \$5.1 million. In addition, revenue from all metered lots in the airport totaled \$1.55 million. The estimated annual cost of operating the proposed lot is \$550,000-\$600,000, plus the cost of operating the metered areas (repairs, accounting staff time and < \$.01 per ticket to collect monies). With a previously estimated total project cost of \$10.63 million (or \$12.31 million assuming an increase in costs of 5% per year), plus \$100,000-200,000 for design updating and rechecks, the cost of replacing Parking Structure 6 should be recovered fairly quickly. Using an assumption of \$4 million in annual revenues and excluding the (minor) cost of operating the meters, the structure would pay for itself in 3.6-3.7 years. This does not account for the time value of the capital.

Other Issues

LAX Master Plan Within the next two years, a new Master Plan may be adopted for LAX. This Master Plan could lead to the ultimate replacement of the entire CTA with new passenger terminals in a different location. However, this will not happen for many years and, in the lengthy interim, Parking Structure 6 will easily pay for itself as well as substantially reduce congestion caused by inadequate parking facilities in the CTA.

LAX Safety - Project Status Report
JULY 2003

Project Name: **AUTOMATIC EXTERNAL DEFIBRILLATOR INSTALLATION**
 Priority: **CONSTRUCTION**
 Project File No.: 01009
 Description: This project will install automatic external defibrillators throughout the terminal buildings.
 Project Engineer: Cynthia Stoker
 Total Project Cost: \$1,700,000
 Estimated Construction Cost: \$1,500,000
 Architect/Engineer: Gruen Associates
 Other Consultants:
 Estimated Design Completion Date: January 2003
 Estimated Construction Start Date: December 2003
 Estimated Construction Completion Date: June 2004
 Comments: The Board approved cabinets and other equipment purchases.

 Project Name: **SKYCHEF DRIVE TRAFFIC SIGNAL**
 Priority: **CONSTRUCTION**
 Project File No.: 00010
 Description: This project will install a traffic signal at the intersection of World Way West and Skychef Drive.
 Project Engineer: Jose (Ernie) Robledo
 Total Project Cost: \$115,000
 Estimated Construction Cost: \$79,000
 Architect/Engineer: Consolidated A/E/S Inc.
 Design Completion Date: August 2001
 Estimated Construction Start Date: April 2003
 Estimated Construction Completion Date: September 2003
 Comments: The Notice to Proceed was issued in April 2003 and the project is 90% complete.

 Project Name: **TBIT FIRE/LIFE SAFETY UPGRADE**
 Priority: **CONSTRUCTION**
 Project File No.: 02002
 Description: This project will repair the fire/life safety system in TBIT to be code compliant.
 Project Engineer: Chris Grossi
 Total Project Cost: \$1,900,000
 Estimated Construction Cost: \$1,400,000
 Architect/Engineer: Leo A. Daly
 Other Consultant(s): TMAD, Schirmer
 Estimated Design Completion Date: March 2003
 Estimated Construction Start Date: September 2003
 Estimated Construction Completion Date: March 2004
 Comments: Award of contract is scheduled for September 2003.

 Project Name: **CENTER TAXIWAY IMPROVEMENT PROGRAM**
 Priority: **DESIGN - Very High**
 Project File No.: TBD
 Description: This project will provide a new center taxiway between Runways 25L-8R and 25R-8L, relocation of Runway 25L-8R and relocation of numerous navigational aids.
 Project Engineer: Van Thompson
 Total Project Cost: \$240,000,000
 Estimated Construction Cost: \$171,000,000
 Architect/Engineer: HNTB
 Design Completion Date: January 2004
 Estimated Construction Start Date: November 2004
 Estimated Construction Completion Date: December 2005
 Comments: HNTB commenced design in June 2003.

LAX Safety - Project Status Report
JULY 2003

Project Name: **LAWA UTILITIES SURVEY AND DOCUMENTATION (LUSAD)**
Priority: **DESIGN - Very High**
Project File No.: 02003
Description: This project will provide a comprehensive survey and GIS documentation of the underground utilities at LAX, ONT, VNY and PMD.
Project Engineer: Phil Lauri
Phase II: \$8,000,000
Total Project Costs to Date: \$9,500,000
Architect/Engineer: Carter Burgess
Other Consultant(s):
Estimated Design Completion Date: October 2002
Phase II Start Date: August 2003
Estimated Construction Completion Date: June 2005
Comments: The Phase II Contract Amendment has been negotiated and was approved by BOAC on April 1, 2003. Phase II NTP is expected in August 2003.

Project Name: **SOUTHSIDE RUNWAY IMPROVEMENT PROGRAM & NLA INTEGRATED STUDY**
Priority: **DESIGN - Very High**
Project File No.: TBD
Description: This project will improve the southside runway system and evaluate the requirements and impacts of accommodating the New Large Aircraft (NLA) at LAX.
Project Engineer: Van Thompson/Larry Hsu
Total Project Cost: \$1,381,330 (Study only)
Estimated Construction Cost: TBD
Architect/Engineer: HNTB
Other Consultant(s): NASA/AMES
Estimated Design Completion Date: July 2003 (Study Only)
Estimated Construction Start Date: TBD
Estimated Construction Completion Date: TBD
Comments: Board awarded a contract to HNTB to study various alternatives of the south runway complex and airfield accommodation of the new large aircraft. The study with recommendations is scheduled to be complete in July 2003.

Project Name: **APRON LIGHTING UPGRADE**
Priority: **DESIGN - High**
Project File No.: 01004
Description: This project will improve the lighting at the existing Terminal Building aprons.
Project Engineer: Lih Tsau/Mina Hanna
Total Project Cost: \$7,490,000
Estimated Construction Cost: \$5,885,000
Architect/Engineer: PMD Staff
Other Consultants:
Estimated Design Completion Date: July 2003
Estimated Construction Start Date: January 2004
Estimated Construction Completion Date: August 2004
Comments: Light pole locations have been field checked and approved.

Project Name: **ASDE-X PILOT PROJECT**
Priority: **DESIGN - Medium**
Project File No.: TBD
Description: This project will provide an integrated ground surface movement management system based on technology that will integrate ground and aerial surveillance to provide situational information on a real time basis to operators, managers, and controllers of airside operations.
Project Engineer: Joan Raff
Total Project Cost: \$6,000,000
Architect/Engineer: TBD
Estimated Design Completion Date: December 2003
Estimated Construction Start Date: June 2004
Estimated Construction Completion Date: February 2005
Comments: LAWA has been selected by the FAA to participate in the FAA's AIR-21 Pilot Program to permit cost sharing of Air Traffic Modernization Projects. The FAA share of the program is \$867,000. LAWA's consulting firm is no longer in business. LAWA staff is working with the FAA to draft a Memorandum of Agreement (MOA) and secure the services of another consulting firm. The program will be separated into two phases with the initial phase to complete a site survey and identify program cost.

LAX Safety - Project Status Report
JULY 2003

Project Name: **FIRE STATION 80 SHELTER**
Priority: **DESIGN - Medium**
Project File No.: TBD
Description: This project will provide a roof space for several AARF vehicles.
Project Engineer: Tomas Majewski
Total Project Cost: \$500,000
Estimated Construction Cost: \$393,000
Architect/Engineer: Gruen
Other Consultant(s):
Estimated Design Completion Date: TBD
Estimated Construction Start Date: TBD
Estimated Construction Completion Date: TBD
Comments: Gruen will submit a quote for a revised scope of work. Project will only include a basic shelter. Awaiting new design proposal from Gruen.

Project Name: **WIDENING OF WORLD WAY AT TBIT (LOWER LEVEL)**
Priority: **DESIGN - Medium**
Project File No.: 99008
Description: This project will widen World Way (West End) on the parking structure side opposite of TBIT (lower level) to provide an additional traffic lane.
Project Engineer: Jose (Ernie) Robledo
Total Project Cost: \$600,000
Estimated Construction Cost: \$455,000
Architect/Engineer: TBD
Estimated Design Completion Date: TBD
Estimated Construction Start Date: TBD
Estimated Construction Completion Date: TBD
Comments: Preliminary plans are 90% complete. A design consultant for the storm drain improvements is to be selected. The project is on hold at this time.

Chapter 3 - Land Use

GOALS, OBJECTIVES AND POLICIES

ISSUE TWO: USES, DENSITY, AND CHARACTER

REGIONAL CENTERS

Definition

Regional centers are intended to serve as the focal points of regional commerce, identity, and activity. They cater to many neighborhoods and communities and serve a population of 250,000 to 500,000 residents.

They contain a diversity of uses such as corporate and professional offices, retail commercial malls, government buildings, major health facilities, major entertainment and cultural facilities and supporting services. Region-serving retail commercial malls and retail services should be integrated where they complement and support the other uses in the regional center. The development of sites and structures integrating housing with commercial uses is encouraged in concert with supporting services, recreational uses, open spaces, and amenities.

Regional centers, typically, provide a significant number of jobs and many non-work destinations that generate and attract a high number of vehicular trips. Consequently, each center shall function as a hub of regional bus or rail transit both day and night. Good quality street, area, and pedestrian lighting is essential to generating feelings of safety, comfort, and well being necessary for ensuring public nighttime use of transit facilities.

They are typically high-density places whose physical form is substantially differentiated from the lower-density neighborhoods of the City. Generally, regional centers will range from FAR 1.5:1 to 6:1 and are characterized by six- to twenty-story (or higher) buildings as determined in the community plan. Their densities and functions support the development of a comprehensive and inter-connected network of public transit and services.

Physically, the regional centers are generally characterized by three forms of development

1. Areas containing mid- and high-rise structures concentrated along arterial or secondary highway street frontages (e.g., Wilshire and Hollywood Boulevards). The intensity of activity and incorporation of retail uses in the ground floor of these structures should induce considerable pedestrian activity.
2. Areas containing mid- and high-rise structures sited on large independent lots, set back from the property frontages (e.g., Warner Center and most of Century City). Though inhibited by the separation of structures, it is encouraged that buildings and sites be designed to improve pedestrian activity within the center.

3. Areas containing retail commercial "malls," characterized by low- and mid-rise buildings clustered around common pedestrian areas. It is encouraged that these buildings be sited and designed to improve their relationships to their principal street frontages, enhancing pedestrian activity.

GOAL 3F

Mixed-use centers that provide jobs, entertainment, culture, and serve the region.

Objective 3.10

Reinforce existing and encourage the development of new regional centers that accommodate a broad range of uses that serve, provide job opportunities, and are accessible to the region, are compatible with adjacent land uses, and are developed to enhance urban lifestyles.

Regional Centers: Sherman Oaks

Century City

Policies

Uses and Density

3.10.1 Accommodate land uses that serve a regional market in areas designated as "Regional Center" in accordance with Tables 3-1 and 3-6. Retail uses and services that support and are integrated with the primary uses shall be permitted. The range and densities/intensities of uses permitted in any area shall be identified in the community plans. (P1, P18)

Table 3-6

Land Use Designation	Corresponding Zones
Regional Center	CR, C1.5, C4, [Q]C2

3.10.2 Accommodate and encourage the development of multi-modal transportation centers, where appropriate. (P4, P18, P52)

Design and Development

- 3.10.3 Promote the development of high-activity areas in appropriate locations that are designed to induce pedestrian activity, in accordance with Pedestrian-Oriented District Policies 3.16.1 through 3.16.3, and provide adequate transitions with adjacent residential uses at the edges of the centers. (P1, P18, P24)
- 3.10.4 Provide for the development of public streetscape improvements, where appropriate. (P30, P31, P32)
- 3.10.5 Support the development of small parks incorporating pedestrian-oriented plazas, benches, other streetscape amenities and, where appropriate, landscaped play areas. (P2, P31, P66)
- 3.10.6 Require that Regional Centers be lighted to standards appropriate for nighttime access and use. (P17, P18, P24, P48)

Regional center incorporating retail, offices, and housing (on upper floors) with enhanced pedestrian character. buildings sited along sidewalk, pedestrian-amenities) Characteristics of regional centers: buildings on street frontage, inclusion of small parks, retail and restaurants located on the ground floor.

Questions dog LAX safety operations

SECURITY: Airport officials say the facility is more secure than ever. Others point to what they call possible flaws.

By Ian Gregor DAILY BREEZE

Two years after the Sept. 11 terror attacks, the front door to Los Angeles International Airport is more heavily fortified than ever.

A new federal screening force electronically checks all luggage for explosives. Passengers pass through unprecedented layers of security. Access to airplane gates is limited. More uniformed and undercover police officers and bomb-sniffing dogs patrol the airport terminals and the airfield perimeter.

"Airports are so much more secure than they ever have been," said Michael Di Girolamo, LAX's deputy executive director of airport operations.

"The fact of the matter is we have not had an incident since 9-11," he said. "I think that's a clear indication of positive efforts by (the Department of) Homeland Security, by airports to make sure airports are secure."

But some aviation experts say critical security holes remain, especially in air cargo, as highlighted this week when a man shipped himself in a box from New York to Texas. Moreover, cleaning crews and other workers are allowed onto airplanes without passing through security, and planes face potential threats from shoulder-fired missiles.

Passengers have been lulled into a false sense of security by the visible and effective improvements in passenger and baggage screening, said Dawn Deeks, spokeswoman for the Association of Flight Attendants.

“What they don’t see is what happens in back of the airport,” Deeks said.

Federal officials counter that the aviation system is blanketed with redundant layers of security that make it difficult for anyone to blow up a plane or use one as a weapon.

“We’re confident that the system of systems we have in place will protect the traveling public,” said Nico Melendez, a spokesman for the federal Transportation Security Administration.

Billions spent

The TSA, which Congress created after the terror attacks, has spent \$10.6 billion to rebuild the nation’s aviation security system, Melendez said.

Nowhere has the effort been more intense than at LAX, which screens the most departing passengers of any airport and about 150,000 suitcases a day.

TSA has spent tens of millions of dollars deploying a 2,400-member security screening force at LAX — the largest of any U.S. airport — and buying and installing dozens of new \$1 million explosive detection machines. LAX has spent more than \$100 million on renovations for explosive detection machines, more police officers and better airfield perimeter security.

The two agencies are collaborating on a \$313 million project to remove explosive detection machines from terminal lobbies and integrate them into the conveyor belt system that carries bags from airline ticket counters to airplane cargo areas, with the TSA picking up 75 percent of the tab.

But cargo security remains a weak point, experts say.

Fifty percent of the cargo that flows through LAX is in the bellies of passenger planes, but little is inspected. Instead, security largely depends on the

“known shipper” program, which allows only companies that have established relationships with air carriers and freight forwarders to ship cargo.

A General Accounting Office study released in early 2003 found that the program was riddled with procedural and safety violations.

The carrier that shipped the man from New York to Texas apparently followed all protocols because the sender was a known shipper, said Jon Russell, a United Airlines captain based at LAX and regional safety chairman for the Airline Pilots Association.

“I think it’s safe to say the current program has flaws in it,” Russell said. “We have vulnerabilities out there that have to be addressed.”

Proposal stalled

A tough air cargo security bill introduced by U.S. Sens. Dianne Feinstein, D-California, and Kay Bailey Hutchison, R-Texas, passed the Senate but is sitting in the House Committee on Transportation and Infrastructure.

“If you don’t know what’s in the belly of the plane, you’re not safe,” said Deeks, the flight attendant union spokeswoman.

Melendez, the TSA spokesman, said the agency has strengthened the known shipper program, moved to limit what can be shipped in passenger planes, uses dogs at 16 airports including LAX to screen air mail and has teams in place at 30 airports to evaluate cargo processing and identify weak areas.

The agency’s goal is to screen all cargo, but there isn’t adequate scanning technology to penetrate big pallets, he said.

“We’re moving on cargo security (but) we still have work to do there,” Melendez said.

Another security hole, some experts say, is that while pilots and flight attendants undergo the same screening as passengers, catering workers, airplane cleaning crews and mechanics don’t. Criminal background checks, which have been conducted on all workers at LAX who have access to secure parts

of the airport, don't predict what people may do in the future, critics say.

Melendez said flight crews, canine units and "other resources available to the TSA" sweep planes before they take off. An aviation security expert, who asked not to be identified, said it would be difficult for workers to smuggle weapons or bombs aboard planes because they are constantly observed by airline officials and law enforcement personnel.

"If one measure doesn't catch it, we're confident the next measure will," Melendez said.

LAX security hiring program lags

By Ian Gregor

DAILY BREEZE

Federal officials must hire and train up to 3,500 new security workers for Los Angeles International Airport and have most on the job by the end of the year to meet a congressional deadline established after Sept. 11.

But seven months after President Bush signed the legislation, the Transportation Security Administration has yet to announce a security director for LAX or to advertise jobs for the new passenger and baggage screeners, who will replace private companies that worked directly for airlines. Some experts question whether the agency will be able to meet its hiring deadline.

"We think it can happen" on time, said one aviation official, who asked not to be identified.

"The question is whether it will happen on time."

TSA spokesman Greg Warren said the agency will meet the deadline because it has contracted with private companies to hire and train the workers.

"We're on pace to meet our congressional mandates," Warren said. "We're confident it can be done."

One official familiar with the hiring process said he

expects the TSA will announce a new LAX security director within two weeks. Korn/Ferry International, the executive search firm that the TSA hired to help recruit the security directors, no longer has the LAX job posted on its Web site.

Transportation Secretary Norman Mineta said the hiring may have slowed in some cases because of a desire to ensure a diverse pool of applicants in terms of gender, race, ethnicity and job experience.

At an airport like LAX, "it's a highly visible job," Mineta said during a Washington, D.C., press briefing Thursday.

"You want to make sure you have a good person," Mineta said.

While plenty of attention has been focused on the government's struggle to buy and install enough \$1 million explosives detection machines for the nation's 429 commercial airports, an equally daunting task is hiring and training 30,000 to 35,000 security workers to operate the equipment and staff passenger screening checkpoints.

Several aviation experts said they believe LAX will need 3,000 to 3,500 security personnel. Labor union leaders estimate that fewer than 40 percent of the 1,000 current LAX screeners have U.S. citizenship, which is required for TSA employment.

LAX will need about 1,200 people to screen air travelers at 10 checkpoints in the nine passenger terminals; 800 to 1,000 screen luggage; 300 to 500 to replace LAX police officers who currently observe passengers at screening checkpoints and respond to problems; and 300 to 800 people to screen airport workers as they enter secure areas of the airport and airfield, according to experts' estimates.

Passenger screeners must be in place by Nov. 19 and baggage screeners by Dec. 31, said Warren, the TSA spokesman.

The TSA contracted with Minneapolis-based NCS Pearson to hire the security workers, who will earn \$23,600 to \$35,400 a year, plus cost of living adjustments. Lockheed Martin will train the passenger screeners and develop overall airport security plans, while Boeing Co. will train the baggage screeners.

Jack Keady, an aviation consultant from Playa del Rey, said he believes the TSA can accomplish the task.

“They're going to have to move and move fast but to me it's doable especially if they're willing to hire more of the existing personnel,” Keady said.

The TSA established a pilot hiring program at Baltimore-Washington International Airport earlier this year and started advertising jobs at 30 airports on Friday. The list included major airports in New York, Boston, Atlanta and Chicago, but not LAX.

The TSA on Thursday also announced plans to deploy security checkpoint design teams to up to 120 airports, including LAX, by the first week of July.

The moves mark the start of “more of an action phase, so you should see quicker results, and simultaneously in a lot of areas at once,” a Department of Transportation official said.

LAX officials estimate they will have to spend \$45 million to \$135 million to renovate the airport to accommodate close to 100 minivan-sized explosive detection machines, which use CAT scan technology to determine whether objects inside suitcases are potential bombs. Airport consultants are completing renovation scenarios that will be submitted to the eventual TSA director for consideration.

Thirteen of the machines are in use at LAX.

The TSA has acknowledged that it won't meet the congressional goal of sending every checked piece of luggage through an explosives detection machine by Dec. 31. Instead, the agency plans to screen bags using a combination of 1,100 explosive detection machines and 4,700 to 6,000 machines that detect bags for traces of explosives.

British officials, however, have said that so-called trace detection machines are not accurate.

The TSA has ordered 800 explosives detection machines — 500 from Newark, Calif.-based InVision Technologies and 300 from Clearwater, Fla.-based L-3.

Screeners at LAX have job security

CUTBACKS: Local layoffs won't be needed because of attrition. Workers from other elsewhere may be able to transfer.

By Ian Gregor
DAILY BREEZE

No federal security screeners at Los Angeles International Airport will lose their jobs as a result of nationwide layoffs because LAX's work force has already shrunk from attrition, a federal official said Thursday.

The Transportation Security Administration announced Wednesday that the agency will eliminate 6,000 of its 56,000 screener jobs nationwide by the end of September, including 154 at LAX. But David Stone, LAX's federal security director, said the airport already has fewer screeners than authorized.

The TSA, in recalculating its screener deployments, authorized LAX for up to 2,695 passenger and baggage screeners, but the airport currently has 2,677, Stone said.

"The message for them is if they do their job and do it well they have a job at LAX," Stone said. "There are no layoffs. There are no pink slips."

LAX, in fact, may be able to take on some screeners who may be laid off at airports in Long Beach, Ontario and Orange County, he said.

"We'll see if there's an opportunity to transfer some of their folks to LAX so they don't have to lose their jobs," Stone said.

The decision to trim the screening force, which was announced by Adm. James Loy, the TSA administrator, was not unexpected because the agency exceeded its initial screener projections and budget, angering some members of Congress.

Loy also announced that airports no longer will have to post police officers at passenger screening checkpoints — a requirement the TSA mandated after the terror attacks and largely funded.

LAX has stationed officers at checkpoints in all nine terminals since August 1998, airport spokeswoman Nancy Castles said. At that time, following a spate of security breaches and terminal evacuations, the Los Angeles City Council passed a resolution recommending a police presence at the locations.

Stone said he would like LAX to retain officers at checkpoints. The TSA will continue to pay for checkpoint officers at some airports, he said, adding that he will lobby for LAX to get the funding if airport officials want to continue the deployment.

“If there’s any airport that should keep these (checkpoint officers) this is it,” Stone said.

LAX is waiting for a specific policy directive from the TSA before a decision is made on keeping officers at the checkpoints, Castles said. Airport officials also are examining the cost of retaining the officers and the possibility of getting federal reimbursement for their salaries, she said.

Home Sales Stay on Fire, Especially in Inland Empire

Number of homes sold in San Bernardino and Riverside sets all-time high. Median price for Southland rises 21%.

By Bonnie Harris
Times Staff Writer

August 21, 2003

The Southern California housing market delivered another strong performance last month, setting an all-time record for sales in the Inland Empire and the 30th consecutive month of double-digit price increases for the entire six-county region.

Yet some real estate experts suspect the region's supercharged market is finally beginning to calm down.

The median price for homes sold in the Southland hit a new record of \$328,000 in July — up 21% from a year earlier — according to figures released Wednesday. In addition, a total of 33,561 new and existing homes were sold, which was the highest monthly sales count in nearly 15 years.

Riverside and San Bernardino counties easily led the region in sales of new homes, with year-over-year increases of 35% and 36%, respectively.

"Clearly, the Inland Empire is the strongest area for growth right now," said John Karevoll, an analyst at DataQuick Information Systems, which compiled the real estate statistics. He said Riverside County alone had more than a third of Southern California's total new-home sales.

Median home prices rose from a year ago in all six counties, with Orange County again fetching top dollar at \$428,000. In July, the median price for new houses and condominiums in Orange County was \$549,000, for existing houses it was \$465,000 and for existing condominiums, \$300,000.

Only Ventura County topped Orange County's median price in any category, with a \$619,000 median price for new homes in July. That was a year-over-year increase of 48%.

LOCAL
+
TOLL

SBC

"It is absolutely crazy," said Veronica Sheffield, a Pacific West Realtors agent in Ventura. "Two months ago, I couldn't imagine [prices] going any higher, and now this. How much more can we honestly expect to see?"

Maybe not much, some agents said. Besides an increase in the number of homes coming onto the market — which typically means fewer bidding wars, lower asking prices and longer sale times — the recent uptick in interest rates also has reduced consumers' buying power.

The average rate for 30-year fixed mortgages rose last week to 6.22%, up almost 1.25 percentage points from its record low in mid-June, according to a weekly survey by the Mortgage Bankers Assn. of America.

Demand for home loans nationwide fell 11% last week to their lowest level in more than a year, the survey showed. And while the decline was led primarily by a drop in refinancing applications, which have fallen more than 70% since May, experts said they expect the interest rates to affect applications for purchase mortgages as well. Already that number has dropped 15% since the end of May, according to the survey.

"I doubt very seriously we're going to see these kinds of monthly price increases and sales numbers much longer," said Scott Gibson, president of real estate firm Coldwell Banker's Los Angeles division. "The market is still strong, and will stay strong, but I believe we've almost reached the peak."

Indeed, Wednesday's housing statistics from DataQuick probably don't reflect the recent jump in interest rates because properties that closed in July had been in escrow for a month or so, when rates were still at or near their lowest levels. More telling, Gibson and others said, would be the monthly figures for August home sales.

In July, though, prices in all categories of homes in Southern California showed strong gains.

Existing single-family homes rose 21% from a year earlier to \$336,000, and new homes climbed 14% to \$378,000. Existing condominiums posted the largest increase, up 22% to \$264,000.

Hot July

The Southern California housing market continued its upward trend in July, especially in the Inland Empire.

Research Report

A PROSPECTIVE STUDY OF SOME EFFECTS OF AIRCRAFT NOISE ON COGNITIVE PERFORMANCE IN SCHOOLCHILDREN

Staffan Hygge,¹ Gary W. Evans,² and Monika Bullinger³¹Centre for Built Environment, University of Gävle, Gävle, Sweden; ²Department of Design and Environmental Analysis and Department of Human Development, Cornell University; and ³Department for Medical Psychology, University of Hamburg, Hamburg, Germany

Abstract—Before the opening of the new Munich International Airport and the termination of the old airport, children near both sites were recruited into aircraft-noise groups (aircraft noise at present or pending) and control groups with no aircraft noise (closely matched for socioeconomic status). A total of 326 children (mean age = 10.4 years) took part in three data-collection waves, one before and two after the switch-over of the airports. After the switch, long-term memory and reading were impaired in the noise group at the new airport, and improved in the formerly noise-exposed group at the old airport. Short-term memory also improved in the latter group after the old airport was closed. At the new airport, speech perception was impaired in the newly noise-exposed group. Mediation analyses suggest that poorer reading was not mediated by speech perception, and that impaired recall was in part mediated by reading.

A consequence of modern means of transportation is widespread noise exposure. In Europe, almost 25% of the population is exposed to equivalent noise levels (L_{eq}) of 65 dBA or more (Berglund & Lindvall, 1995). At this level, annoyance is marked, sleep is disturbed, and some cognitive processes are impaired (Cohen, Evans, Stokols, & Krantz, 1986; Evans & Lepore, 1993; Smith & Jones, 1992). Noise exposure is consistently correlated with reading deficits and may interfere with speech perception and long-term memory in primary-school children (Evans & Lepore, 1993).

The simultaneous opening and closing of the new and former Munich Airport provided us with an unprecedented opportunity to conduct a prospective study of the effects of aircraft noise on children. This is the only prospective study of nonauditory effects of noise on children that has been undertaken. Moreover, cessation of noise at the old airport provided a unique opportunity to assess whether expected, noise-related impairments are reversible. Sociodemographically matched control groups exposed to little aircraft noise were formed at both airports. By testing children in silence and not in everyday-noise settings, we eliminated confounds between chronic versus acute noise. Furthermore, examination of the interplay among attention, memory, and reading over time enabled us to test whether expected noise-related reading deficits could be accounted for by shifts in underlying cognitive processes.

Previous cross-sectional research (Cohen et al., 1986; Cohen, Glass, & Stryker, 1973; Evans & Maxwell, 1997) indicated that noise-related reading deficits might be mediated by a cognitive strategy wherein children become less attentive to auditory stimuli as a way to cope with noise. It is unclear whether such shifts in attentional strategies are general to noise

or specific to speech. Laboratory noise also impairs both long-term memory (Hygge, 1997; Hygge, Boman, & Enmarker, in press) and short-term memory (Hamilton, Hockey, & Rejman, 1977; Hockey, 1979). Both speech perception and memory are related to reading acquisition (Crowder & Wagner, 1992; Mann & Brady, 1988).

In summary, we collected prospective data to assess how children's reading was affected by changes in ambient noise levels caused by modified airport operations. In addition, we investigated two cognitive processes, attention and memory, implicated in prior experimental work on acute noise exposure, and how they relate to speech perception.

METHOD

Design and Subjects

The two experimental groups comprised children who were (old airport) or would be (new airport) exposed to aircraft noise. The two control groups were selected from areas that had little exposure to aircraft noise. The control groups were matched with their respective experimental groups on the basis of sociodemographic characteristics. One wave of data collection started 6 months prior to the changeover of airports, the second wave was 1 year later, and the third wave 2 years later. A total of 326 children participated: 43 in the old-airport, no-noise group; 65 in the old-airport, noise group; 107 in the new-airport, no-noise group; and 111 in the new-airport, noise group. Their ages ranged from 8 to 12 ($M = 10.4$, $SD = 0.85$). The children at the new airport were tested 3 to 5 months before the children at the old airport, but there was no difference in average year of birth. Criteria for taking part in the study were a minimum of 2 years of residence and German fluency, which ruled out confounds with ethnicity. Normal hearing, as assessed by audiometric screening, was also a criterion for participation. The experimental and control groups at the two airports did not differ in age, gender, ethnicity, number of family members, parental occupation, or education, and attrition did not differ among the four groups, $\chi^2(3, N = 326) = 1.64, p > .10$.

Procedure and Materials

At each data-collection wave, the children were tested individually in silence for 1.5 hr on 2 consecutive days in a specially designed temperature-controlled and sound-attenuated mobile laboratory that traveled to their schools. The children worked individually on an array of different tasks. In this article, we present only the cognitive dependent measures. (For data on physiological stress and mental health, see Bullinger, Hygge, Evans, Meis, & von Mackensen, 1999; Evans, Bullinger, & Hygge, 1998; Evans, Hygge, & Bullinger, 1995.)

Address correspondence to Staffan Hygge, Laboratory of Applied Psychology, Centre for Built Environment, University of Gävle, SE-801 76 Gävle, Sweden; e-mail: staffan.hygge@hig.se.

Aircraft Noise and Children

Reading

A standardized German reading test was employed (Bigmaier, 1969). The children read paragraphs and word lists of increasing difficulty. Some of the words in the lists were pseudowords, but phonologically appropriate in German.

Memory

On the first day, the children read a text in intermittent broadband noise at 80 dBA L_{eq} and the number of lines read within the 12-min time limit was noted. On the second day, the children were tested for long-term memory (recall) in silence. We introduced noise exposure during encoding to make the task more difficult. Children's performance on this test is sensitive to acute noise exposure (Hygge, 1997). For the short-term memory test, strings of consonants were presented one per second over headphones. Randomly, the sequence was stopped, and the children were asked to write down as many consonants as they could remember, in the correct position, starting at the end of the sequence. Letters in the correct or adjacent positions were scored as correct. Acute noise is known to impair performance on this task (Hamilton et al., 1977).

Attention

Two indices of general attention were used: visual search and reaction time. The visual search task is sensitive to ventilation noise (Hygge, 1991) and chronic stress (Baum, Gatchel, & Schaeffer, 1983). For this task, the children were presented with 12 complex figures and 5 simple target figures and asked to identify which one of the target figures was embedded in each complex figure. In the reaction time task, the children responded to random occurrences of red and green lights by pressing two different buttons. The children performed this task first in a silent 5-min session and then in an equally long session with aircraft noise at 85 dBA L_{eq} .

Speech perception

The speech perception measure was adapted from Hygge, Rönnerberg, Larshy, and Arlinger (1992). The children heard a story against different noise backgrounds (aircraft noise, road noise, and broadband noise) and used buttons labeled "+" and "-" to adjust the sound level of the story when it dropped randomly by 10 dBA. They were instructed to readjust the volume to the point where they could understand what was said if they concentrated. Noise-exposed children appear to ignore or tune out speech-relevant stimuli (Cohen et al., 1973, 1986; Evans & Maxwell, 1997) and are expected to require better signal-to-noise ratios than children who have not been exposed to noise.

RESULTS

Noise Levels

Noise levels were measured with a Brüel & Kjær (Copenhagen, Denmark) Community noise-level analyzer for a 24-hr period during data collection at the mobile laboratory. The expected changes in noise levels were observed at both airports (see Table 1).

Table 1. Noise levels (24-hr dBA L_{eq}) before and after the airport switch

Airport and group	Before switch (Wave 1)	After switch (Wave 3)
Old airport—aircraft noise	68	54*
Old airport—no aircraft noise	59	55
New airport—aircraft noise	53	62
New airport—no aircraft noise	53	55

*This number is an average from Waves 2 and 3 because there was only one observation in Wave 3, at a suspect value of 49.

Reading

On the word-list part of the reading test, only difficult words showed differences between the groups (see Fig. 1). The Airport \times Group \times Wave interaction was significant, $F(2, 252) = 5.10, p = .007$. (All F tests with repeated measures of wave were treated with multivariate analyses of variance, MANOVAs, rather than univariate analyses of variance, ANOVAs. These MANOVAs yield higher p values.

Fig. 1. Mean number of errors on the difficult word list as a function of airport, noise group, and measurement wave. Error bars show standard errors of the means.

and thus are more conservative, than the corresponding univariate epsilon-corrected Greenhouse-Geisser ANOVAs.) Separate *t* tests (two-tailed throughout, except as noted) showed a difference between groups at the old airport at Wave 1, $t(99) = 2.68, p = .009$, but not at Waves 2 and 3 ($ts < 1$). At the new airport, there was a marginal difference between groups at Wave 3, $t(154) = 1.80, p = .074$, but not at Waves 1 and 2 ($ts < 1$).

The results for the prose component of the reading test were similar to those for the word-list test, but not as marked. For the most difficult paragraphs (Numbers 8–12), there was a weak Airport \times Group \times Wave interaction, $F(2, 172) = 2.16, p = .118$ (see Fig. 2). Separate *t* tests revealed a difference between groups at the old airport at Wave 1, $t(82) = 2.79, p = .007$, but not at Waves 2 and 3 ($ts < 1$). At the new airport there were no significant effects.

Memory

On the long-term recall task (see Fig. 3), there was a significant Airport \times Group \times Wave interaction, $F(2, 311) = 4.25, p = .015$. Separate *t* tests showed a marginally significant difference between groups at the old airport at Wave 1, $t(104) = 1.88, p = .062$, one-tailed, but not at Waves 2 and 3 ($ts < 1.28$). At the new airport, there was a difference between groups at Wave 3, $t(208) = 2.72, p = .007$, but not at Waves 1

Fig. 2. Mean number of errors on the difficult paragraphs in the reading test as a function of airport, noise group, and measurement wave. Error bars show standard errors of the means.

Fig. 3. Mean score on the long-term memory task as a function of airport, noise group, and measurement wave. Error bars show standard errors of the means.

and 2 ($ts < 1.12$). For the number of lines completed, there were no noise effects.

At the old airport, the short-term memory test showed a significant Group \times Wave interaction, $F(2, 203) = 5.97, p = .004$. The poorer short-term memory performance of the noise group recovered to reach the level of the control group's performance at Waves 2 and 3 (see Fig. 4). Separate *t* tests showed tendencies toward more correct responses in the no-noise group than in the noise group at Wave 1, $t(104) = 1.70, p = .092$; the difference was in the opposite direction at Wave 2, $t(104) = 1.63, p = .108$, and there was no difference between groups at Wave 3. At the new airport, there were no differences between the groups across the waves.

Attention

For the embedded-figures task, there were no reliable interactions involving chronic aircraft noise over time.

For the reaction time task, a MANOVA of reaction time and errors together yielded an Airport \times Group \times Wave interaction, $F(4, 179) = 5.58, p = .004$. Performing the task in acute noise or no noise did not qualify this interaction, and there was no main effect of acute noise, $F_s < 1$. Only reaction time, not errors, contributed to the interaction. The aircraft-noise group at the old airport was slower than its control group

Aircraft Noise and Children

Fig. 4. Mean proportion of correct items on the short-term memory task as a function of airport, noise group, and measurement wave. Error bars show standard errors of the means.

Fig. 5. Mean dB ratio of speech to noise on the speech perception task as a function of airport, noise group, and measurement wave. Error bars show standard errors of the means.

at Wave 2, $t(61) = 2.29, p = .026$, but not at the other waves ($t_s < 1.34$). At the new airport, the aircraft-noise group was slower than the no-aircraft-noise group at Wave 3, $t(121) = 2.09, p = .039$.

Speech Perception

Because of apparatus failure and resulting low n_s , data from Wave 2 on the speech perception task were discarded. As Figure 5 shows, speech perception improved from Wave 1 to Wave 3 at the old airport, but there was no differential improvement between the groups. At the new airport, the onset of aircraft noise seemed to block improvement in auditory discrimination from Wave 1 to Wave 3, as evidenced by the Group \times Wave interaction, $F(3, 150) = 7.63, p = .000$.

Mediation

To probe for mediation, we entered into path analyses (LISREL; Jöreskog & Sörbom, 1996) the difference scores between performance in the last and first measurement waves for the paragraph reading task, the difficult word list, the long-term memory task, the number of lines completed, the short-term memory task, and the speech perception task. The results of these path analyses were straightforward and showed a

very good fit between data from both airports and one of the models (see Fig. 6). Good fits were indicated by both a high p value ($>.05$) for chi-square and a low value of the root mean square error of approximation ($<.08$; Jöreskog & Sörbom, 1996). In this model, the noise effect on the reading tasks was not mediated by memory or speech perception. For long-term memory, there was a partial mediation by the word-list component of the reading task. For all the other tested variables in different combinations there were no indications of mediating links. The value of N in this analysis was low, mainly because of participants not finishing the difficult reading paragraphs in Wave 1. However, path analyses not including reading, and thus having a higher N , yielded path coefficients between the other variables that were of approximately the same strength as shown in Figure 6.

DISCUSSION

These longitudinal data complement nearly 20 cross-sectional studies showing adverse impacts of aircraft noise on reading in elementary school children. Moreover, these effects occur prospectively and may be reversible. We have also demonstrated prospective impacts of chronic noise on long-term memory. More work is needed to determine the sensitivity of this effect to the duration of exposure, as well as children's age-

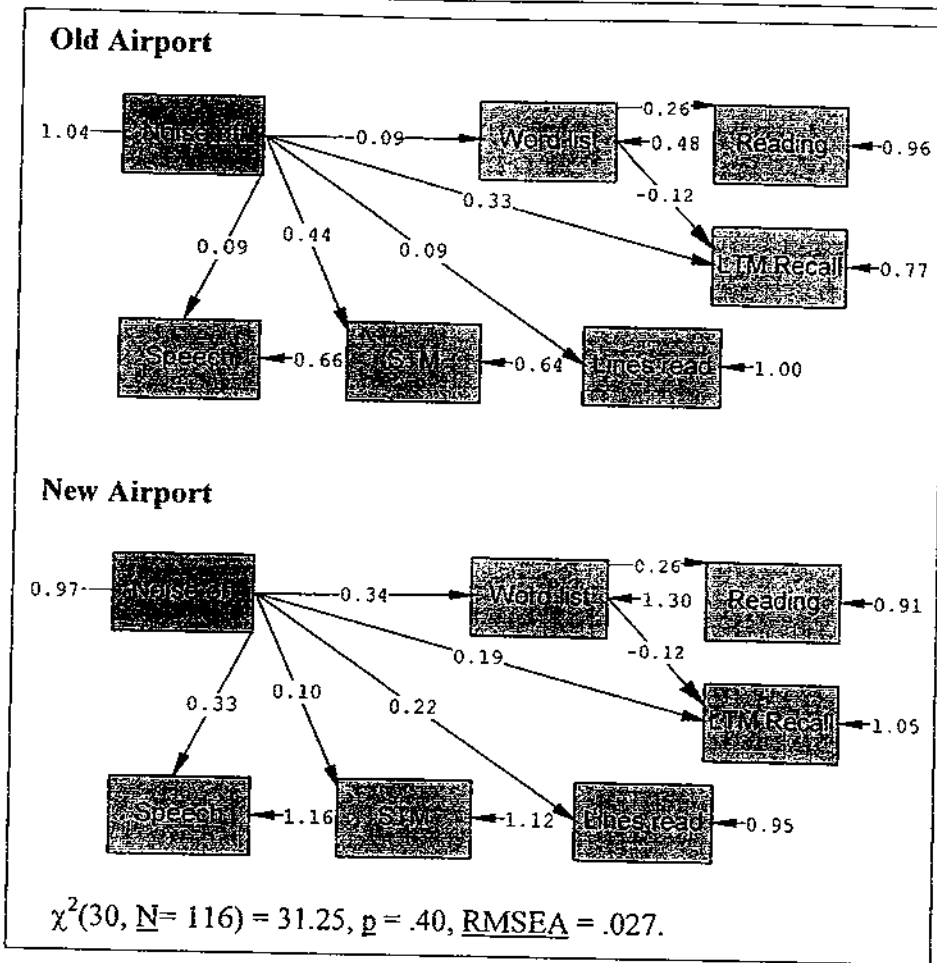

Fig. 6. Model fit (chi-square and root mean square error of approximation, RMSEA) and standardized path coefficients between cognitive measures. The cognitive measures were calculated as difference scores between the last and first measurement waves for the difficult word list ("Word list"), the paragraph reading task ("Reading"), the long-term memory task ("LTM Recall"), the number of lines completed ("Lines read"), the short-term memory task ("STM"), and the speech perception task ("Speech"). The paths from Word list to Reading (0.26) and LTM Recall (-0.12), with values in smaller print, were constrained to be equal at the two airports.

This is also the first study to show prospective impacts of chronic noise on a cognitive process, long-term memory. Weaker evidence suggests noise-induced deficiencies in speech perception and short-term memory.

Reading and long-term memory effects replicated, disappearing when the old airport closed and emerging after the new airport opened. This provides strong causal evidence for the vulnerability of central language processing to noise exposure, and the reversible nature of the impact. Additional research is needed to see whether the adverse noise effects on reading and recall continue over time. Note that at the new airport the negative effects were stronger at Wave 3 than at Wave 2, which suggests a cumulative noise effect.

The speech perception findings warrant further research. Differences in speech perception did not mediate noise effects on reading. The lack of mediation is inconsistent with prior cross-sectional studies (Cohen et al., 1973, 1986; Evans & Maxwell, 1997). The present longitudinal data raise doubts about the validity of inattention, or "tuning out," as an explanatory mechanism for the adverse impacts of noise on reading performance.

Furthermore, although children's reading worsened with cumulative noise exposure at the new airport and recovered following noise cessation at the old airport, speech perception deficits among noise-exposed children at the old airport did not recover. This suggests that speech perception did not mediate the noise effects on reading, a conclusion that is also indicated by the structural equation results. An explanation for this pattern of results may be the developmental timing of the noise exposure. Perhaps noise exposure damages the development of speech perception in different ways during the early and late portions of the reading-acquisition period.

Future research needs to address the importance of both the developmental timing and the duration of noise exposure in determining the effect of noise on reading and cognitive development. Research also needs to sample a wider range of noise levels in order to generate a dose-response function for reading, which would provide additional basic evidence and better inform public policy for noise protection of children.

Acknowledgments—This study was conducted while Staffan Hygge was with the National Swedish Institute for Building Research and with Kungl Tekniska Högskolan—Royal Institute of Technology, both in Gävle, Sweden. We are grateful to the families who cooperated with this research. We thank Gerhard Helm, Sylvia von Mackensen, Markus Meis, Gunnar Söderqvist, and Christian Wigren for their dedication to the project. This research was partially supported by the Society for the Psychological Study of Social Issues, the National Institute of Health (R01 HL 4732 01A), the National Institute of Child Health and Human Development (1 F33 HD 08473-01), the Nordic Scientific Group for Noise Effects, the Swedish Environmental Protection Agency, the German Research Foundation (DFG), and the National Swedish Institute for Building Research. The third author was also supported by a DFG Heisenberg Fellowship. We are particularly grateful to Nils Antoni, former director of the National Swedish Institute for Building Research, who efficiently made necessary funds available at the outset of the Munich study.

Mr. Jim Ritchie
City of Los Angeles
Los Angeles World Airports
Master Plan Office
P.O. Box 92216
Los Angeles, CA 90009-2216

**Re: Public Records Act Request for Materials Relating to the
Supplement to the Draft EIS/EIR for the Los Angeles
International Airport Proposed Master Plan Improvements**

Dear Mr. Ritchie:

On behalf of the City of El Segundo, this is a request pursuant to the California Public Records Act, Gov. Code § 6250 *et seq.*, for the release and production of the records identified below. These materials were used in the preparation of the Supplement to the Draft EIS/EIR for the LAX Master Plan ("Supplement"), and are necessary for the City and its expert technical consultants to complete their analysis of the air quality analysis and human health risk assessment contained in that Supplement.

1. All data used to provide the estimates for air pollutant background concentrations and emissions set forth in Supplement, Tables S4.6-2, S4.6-6, S4.6-7, S4.6-9, S4.6-10, S4.6-11, S4.6-12, S4.6-13, S4.6-19, S4.6-20, S4.6-21, S4.6-22, and S4.6-27. Specifically, we are requesting the input and output files used to generate the results published in the Supplement. Based on the information regarding modeling that was provided in the Supplement, we are requesting the following, in a hard copy and electronic format:

- EDMS 3.2 input/output files for all alternatives
- EDMS 4.11 input/output files

SAL00015 V

Mr. Jim Ritchie
October 16, 2003
Page 2

- ISCST3 input/output files
- CALMPRO input/output files
- CAL3QHCR input/output files
- EMFAC 2002 input/output files
- ARM and ISC3-OLM input/output files
- AIRMET input/output files (1996 AERMOD format meteorological dataset)
- Meteorological data set and one year of ozone data for SCAQMD (Referred to at p. 4-359 of Supplement, footnotes 113 and 114)
- 3 years of hourly monitored data collected at SCAQMD Monitoring Station No. 094, and 7 months of hourly monitored data collected at LAX downwind of Runway 25R (see Attachment Q in Technical Report S-4)

2. The modified ISC3-OLM (version 96113) air dispersion model, which the Supplement describes as having been modified to include the ISCS3T (version 02035) model and algorithms (see Supplement, p 4-359). According to the Supplement, this model was utilized in determining impacts but was not made available in the materials provided with the Supplement.

3. All data used to estimate toxic pollutant emissions modeled in the risk assessments summarized in the Supplement at Tables S4.24.1-1 through S4.24.1-6. In particular, we are requesting the input/output files used for modeling. Please provide these data in a hard copy and electronic format.

We request that these materials be provided by means that will facilitate their use by our consultants. In June 2001, responding to a similar Public Records Act request by El Segundo, LAWA provided us with a compact disk containing similar materials for the January 2001 Draft EIS/EIR for the Master Plan. The files on that disk were use-protected, which prevented El Segundo's technical consultants from verifying the calculations used in the environmental analysis. We are therefore requesting that the data be provided without use-protection, to allow our consultants to complete their analysis.

If you determine to withhold any responsive records, please provide us with a log that describes such records and the basis for your determination that such records are exempt from mandatory disclosure.

The City of El Segundo is also submitting a Freedom of Information Act request to the Federal Aviation Administration. A copy of that letter is attached.

**Re: Freedom of Information Act Request for Materials Relating to
the Supplement to the Draft EIS/EIR for the Los Angeles
International Airport Proposed Master Plan Improvements**

Dear Mr. Kessler:

On behalf of the City of El Segundo, this is a request pursuant to the Freedom of Information Act, 5 U.S.C. § 552, for the release and production of the records and materials identified below. These materials were used in the preparation of the Supplement to the Draft EIS/EIR for the LAX Master Plan ("Supplement"), and are necessary for the City and its expert technical consultants to complete their analysis of the air quality analysis and human health risk assessment contained in that Supplement.

1. All data used to provide the estimates for air pollutant background concentrations and emissions set forth in Supplement, Tables S4.6-2, S4.6-6, S4.6-7, S4.6-9, S4.6-10, S4.6-11, S4.6-12, S4.6-13, S4.6-19, S4.6-20, S4.6-21, S4.6-22, and S4.6-27. Specifically, we are requesting the input and output files used to generate the results published in the Supplement. Based on the information regarding modeling that was provided in the Supplement, we are requesting the following, in a hard copy and electronic format:

SAL00015 V

Mr. David Kessler

October 16, 2003

Page 2

- EDMS 3.2 input/output files for all alternatives
- EDMS 4.11 input/output files
- ISCST3 input/output files
- CALMPRO input/output files
- CAL3QHCR input/output files
- EMFAC 2002 input/output files
- ARM and ISC3-OLM input/output files
- AIRMET input/output files (1996 AERMOD format meteorological dataset)
- Meteorological data set and one year of ozone data for SCAQMD (Referred to at p. 4-359 of Supplement, footnotes 113 and 114)
- 3 years of hourly monitored data collected at SCAQMD Monitoring Station No. 094, and 7 months of hourly monitored data collected at LAX downwind of Runway 25R (see Attachment Q in Technical Report S-4)

2. The modified ISC3-OLM (version 96113) air dispersion model, which the Supplement describes as having been modified to include the ISCS3T (version 02035) model and algorithms (see Supplement, p 4-359). According to the Supplement, this model was utilized in determining impacts but was not made available in the materials provided with the Supplement.

3. All data used to estimate toxic pollutant emissions modeled in the risk assessments summarized in the Supplement at Tables S4.24.1-1 through S4.24.1-6. In particular, we are requesting the input/output files used for modeling. Please provide these data in a hard copy and electronic format.

We request that these materials be provided by means that will facilitate their use by our consultants. In June 2001, after making a similar FOIA request, El Segundo was provided with a compact disk containing similar materials for the January 2001 Draft EIS/EIR for the Master Plan. The files on that disk were use-protected, which prevented El Segundo's technical consultants from verifying the calculations used in the environmental analysis. We are therefore requesting that the data be provided without use-protection, to allow our consultants to complete their analysis.

If you determine to withhold any responsive records, please provide us with a log that describes such records and the basis for your determination that such records are exempt from mandatory disclosure.

Mr. David Kessler
October 16, 2003
Page 3

FOIA provides for a waiver or reduction of fees if disclosure "is in the public interest because it is likely to contribute significantly to public understanding of the operations or activities of the government and is not primarily in the commercial interest of the requester." 5 U.S.C. § 552(a)(4)(iii); 49 C.F.R. § 7.97(e). We ask that you waive all search and duplication fees because the parties making this request meet the criteria set forth in these sections and in 49 U.S.C. § 7.97(f). The LAX Master Plan is unquestionably a topic of great public interest in southern California; making these documents available to the public will enhance the public's understanding of the proposed project and its background. The City of El Segundo has no commercial interest that would be furthered by the requested disclosure.

The City of El Segundo is also submitting a Public Records Act request to the Los Angeles World Airports; a copy of that letter is attached.

We certainly appreciate your assistance in this matter. Please contact me as soon as possible to let me know when we can expect to receive the requested documents. If you have any questions about this request, please do not hesitate to give me a call.

Very truly yours,

SHUTE, MIHALY & WEINBERGER LLP

Mr. Jim Ritchie
City of Los Angeles
Los Angeles World Airports
Master Plan Office
P.O. Box 92216
Los Angeles, CA 90009-2216

Re: Second Public Records Act Request for Materials Relating to the Supplement to the Draft EIS/EIR for the Los Angeles International Airport Proposed Master Plan Improvements

Dear Mr. Ritchie:

On behalf of the City of El Segundo, we are submitting this second request pursuant to the California Public Records Act, Gov. Code § 6250 et seq., for the release and production of the records identified below. These materials were used in the preparation of the Supplement to the Draft EIS/EIR for the LAX Master Plan ("Supplement"), and are necessary for the City and its expert technical consultants to complete their analysis of the air quality and water quality sections of that Supplement. We request the following:

1. The input/output files used for estimating construction emissions with CARB's OFFROAD Model, referred to at page 4-358 of the Supplement. We are requesting the data in hard copy and electronic format, in a form that will allow our expert technical consultants to access the data and check the calculations of the modeling.

2. All data, spreadsheets, and calculations used to estimate storm water runoff, pollutant loadings and concentrations, impervious areas, and surface water recharge volumes, as set forth in Tables S4.7-3, S4.7-5, S4.7-6, S4.7-7 of the Supplement, Tables S2 through S12 of the Supplemental Hydrology and Water Quality Technical Report S5

SAL00015

Mr. Jim Ritchie
October 28, 2003
Page 2

and the Tables presented in Attachments A and C.

3. A copy of the documents cited in footnotes on page 1 of the Supplemental Hydrology and Water Quality Technical Report, specifically:

- City of Los Angeles, Los Angeles World Airports, Revised Hydrology Report for Los Angeles International Airport North Perimeter Storm Drain, prepared by Parsons, Brinckerhoff, Quade & Douglas, Inc., December 2001

- City of Los Angeles, Los Angeles World Airports, Final Onsite Hydrology Report for Los Angeles International Airport, prepared by Parsons, Brinckerhoff, Quade & Douglas, Inc. December 2002.

We request that these materials be provided by means that will facilitate their use by our consultants. In June 2001, responding to a similar Public Records Act request by El Segundo, LAWA provided us with a compact disk containing similar materials for the January 2001 Draft EIS/EIR for the Master Plan. The files on that disk were use-protected, preventing El Segundo's technical consultants from verifying the calculations used in the environmental analysis. We request that the data be provided without use-protection, to allow our consultants to complete their analysis.

We have a prior Public Records Act request still pending, submitted by our letter dated October 16. That request specified data used in the Supplement to estimate air pollutant background concentrations and emissions as set forth in the Supplement, Tables S4.6-2, S4.6-6, S4.6-7, S4.6-9, S4.6-10, S4.6-11, S4.6-12, S4.6-13, S4.6-19, S4.6-20, S4.6-21, S4.6-22, and S4.6-27, including the input and output files used to generate the results published in the Supplement, and the modified ISC3-OLM, which is also utilized in the Supplement. We followed up with a telephone call to airport counsel Raymond Igunas last week. We have received no response from LAWA on that request. Please call me or Osa Armi of my office as soon as possible to discuss our information requests.

If you determine to withhold any responsive records, please provide us with a log that describes such records and the basis for your determination that such records are exempt from mandatory disclosure.

The City of El Segundo is also submitting a second Freedom of Information Act request to the Federal Aviation Administration. A copy of that letter is enclosed.

Pursuant to the Public Records Act, please respond to this request within ten calendar days. Gov. Code §6253(c). We appreciate your assistance in this matter. If you

**Re: Second Freedom of Information Act Request for Materials
Relating to the Supplement to the Draft EIS/EIR for the Los
Angeles International Airport Proposed Master Plan
Improvements**

Dear Mr. Kessler:

On behalf of the City of El Segundo, we are submitting this second request pursuant to the Freedom of Information Act, 5 U.S.C. § 552, for the release and production of the records and materials identified below. These materials were used in the preparation of the Supplement to the Draft EIS/EIR for the LAX Master Plan ("Supplement"), and are necessary for the City and its expert technical consultants to complete their analysis of the air quality and water quality sections of the Supplement. We request the following:

1. The input/output files used for estimating construction emissions with CARB's OFFROAD Model, referred to at page 4-358 of the Supplement. We are requesting the data in hard copy and electronic format, in a form that will allow our expert technical consultants to access the data and check the calculations of the modeling.

2. All data, spreadsheets, and calculations used to estimate storm water

SAL00015 V

David Kessler
October 28, 2003
Page 2

runoff, pollutant loadings and concentrations, impervious areas, and surface water recharge volumes, as set forth in Tables S4.7-3, S4.7-5, S4.7-6, S4.7-7 of the Supplement, Tables S2 through S12 of the Supplemental Hydrology and Water Quality Technical Report S-5, and the Tables presented in Attachments A and C.

3. A copy of the documents cited in footnotes on page 1 of the Supplemental Hydrology and Water Quality Technical Report, specifically:

- City of Los Angeles, Los Angeles World Airports, Revised Hydrology Report for Los Angeles International Airport North Perimeter Storm Drain, prepared by Parsons, Brinckerhoff, Quade & Douglas, Inc., December 2001

- City of Los Angeles, Los Angeles World Airports, Final Onsite Hydrology Report for Los Angeles International Airport, prepared by Parsons, Brinckerhoff, Quade & Douglas, Inc. December 2002.

We request that these materials be provided by means that will facilitate their use by our consultants. In June 2001, in response to similar FOIA and California Public Records Act requests by El Segundo, we received a compact disk containing data used in the January 2001 Draft EIS/EIR for the Master Plan. The files on that disk were use-protected, preventing El Segundo's technical consultants from verifying the calculations used in the environmental analysis. We request that the data be provided without use-protection, to allow our consultants to complete their analysis.

Note that we have a prior FOIA request pending, submitted by our letter dated October 16. That request specified data used in the Supplement to estimate air pollutant background concentrations and emissions as set forth in the Supplement, Tables S4.6-2, S4.6-6, S4.6-7, S4.6-9, S4.6-10, S4.6-11, S4.6-12, S4.6-13, S4.6-19, S4.6-20, S4.6-21, S4.6-22, and S4.6-27, including the input and output files used to generate the results published in the Supplement, and the modified ISC3-OLM, which is also utilized in the Supplement. We have received no response from you or anyone in your office. Please call me or Osa Armi of my office as soon as possible to discuss our information requests.

If you determine to withhold any responsive records, please provide us with a log that describes such records and the basis for your determination that such records are exempt from mandatory disclosure.

FOIA provides for a waiver or reduction of fees if disclosure "is in the

SAL00015 V

David Kessler
October 28, 2003
Page 3

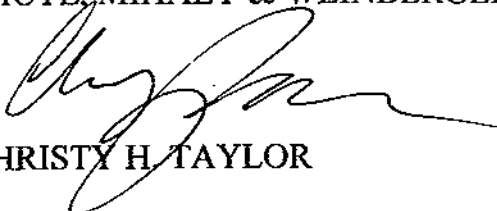

public interest because it is likely to contribute significantly to public understanding of the operations or activities of the government and is not primarily in the commercial interest of the requester." 5 U.S.C. § 552(a)(4)(iii); 49 C.F.R. § 7.97(e). We ask that you waive all search and duplication fees because the parties making this request meet the criteria set forth in these sections and in 49 U.S.C. § 7.97(f). The LAX Master Plan is unquestionably a topic of great public interest in southern California; making these documents available to the public will enhance the public's understanding of the proposed project and its background. The City of El Segundo has no commercial interest that would be furthered by the requested disclosure.

The City of El Segundo is also submitting a second Public Records Act request to Los Angeles World Airports; a copy of that letter is enclosed.

We certainly appreciate your assistance in this matter. Please contact me as soon as possible to let me know when we can expect to receive the requested documents. If you have any questions about this request, please do not hesitate to give me a call.

Very truly yours,

SHUTE, MIHALY & WEINBERGER LLP

CHRISTY H. TAYLOR

THIS AGENDA FOR THE MEETING WAS POSTED OUTSIDE ON THE BOARD OF AIRPORT COMMISSIONERS' BULLETIN BOARD AND THE FRONT DOOR OF THE DEPARTMENT OF AIRPORTS' ADMINISTRATION BUILDING LOBBY, #1 WORLD WAY, P.O. BOX 92216, LOS ANGELES, CALIFORNIA ON THURSDAY, AUGUST 28, 2003 AT 12:10 P.M. FOR PUBLIC REFERENCE.

MINUTES

OF THE MEETING OF THE BOARD OF AIRPORT COMMISSIONERS OF THE CITY OF LOS ANGELES CONVENED IN SPECIAL SESSION IN THE SAMUEL GREENBERG BOARD ROOM NO. 107/116 IN THE ADMINISTRATION BUILDING AT LOS ANGELES INTERNATIONAL AIRPORT, #1 WORLD WAY, P.O. BOX 92216, LOS ANGELES, CALIFORNIA 90009 ON TUESDAY, SEPTEMBER 2, 2003 AT 8:30 A.M.

PRESENT: Commissioners Levine, Llorens, Petersen, Weil and President Stein

Kim R. Day	Interim Executive Director
Paul L. Green	Chief Operating Officer
Michael DiGirolamo	Deputy Executive Director
Samson Mengistu	Deputy Executive Director
Edward J. Ritchie	Deputy Executive Director
Eduardo Angeles	Managing Assistant City Attorney
Sandra J. Miller	Secretary

ABSENT: Commissioners Contreras and Vergara

oOo

In addition to the above listed Executive staff, there were 15 staff members present.

Presentation for approval Minutes of the Special Meeting of August 11, 2003.

APPROVED AS PRESENTED

oOo

Discussion Items: 4, 5, 10, 11, 12, 13 and 17

Discussion begins on page 21

As a covered entity under Title II of the Americans with Disabilities Act, the City of Los Angeles does not discriminate on the basis of disability and, upon request, will provide reasonable accommodation to ensure equal access to its programs, services, and activities.

Discussion: See pages 22 and 23

CONSENT CALENDAR

President Stein requested a motion of approval for the following enumerated items that did not need amendments or further discussion: 1, 3, 8, 16, 18, 19 and 20.

Motion of approval of the consent calendar was made by Commissioner Petersen, seconded by Commissioner Llorens and it was unanimously adopted.

DISCUSSION ITEMS

ITEM 17. IN ACCORDANCE WITH CHARTER SECTION 604, THE BOARD OF AIRPORT COMMISSIONERS APPOINTS KIM DAY, AS INTERIM EXECUTIVE DIRECTOR

President Stein addressed this item by acknowledging that this was a bittersweet day for LAWA to lose such a capable leader and that he didn't know anybody else who could have got us through September 11, 2001; but at the same time there's good news in that we had three extraordinarily qualified candidates who interviewed for the position—Mr. Paul Green, COO; Mr. Jim Ritchie, Deputy Executive Director; and Ms. Kim Day, Deputy Executive Director. President Stein stated with pleasure that the Mayor has chosen, to send forward for Interim Executive Director, Kim Day; which speaks highly of her qualifications, but in no way diminishes the qualifications of Mr. Green and Mr. Ritchie. The Board stated their support of the appointment of Ms. Day.

Ms. Day thanked the Board and stated this was an honor and quite a challenge, but she'll do her best to live up to the faith the Board has shown in her.

ITEM 4. APPROVE THE AWARD OF A CONTRACT TO CSA CONSTRUCTORS, INC. FOR THE CONSTRUCTION OF THE PROJECT ENTITLED "SECURITY PROGRAM – ADDITIONAL SECURITY SCREENING CHECKPOINTS IN TBIT – INTERIM SOLUTION" AT LOS ANGELES INTERNATIONAL AIRPORT

Kim Day, Interim Executive Director, briefed the Board on the history of this item as it related to a previously deferred board report.

ITEM 5. APPROVE AWARD OF A CONTRACT TO STEINY AND COMPANY, INC. FOR THE CONSTRUCTION OF THE PROJECT ENTITLED "TBIT FIRE/LIFE SAFETY UPGRADE" AT LOS ANGELES INTERNATIONAL AIRPORT

The Board inquired why the MBE/WBE participation was so low. Director of Administration Bill Bruce addressed the low participation and the outreach process.

ITEM 10. APPROVE THE THIRD AMENDMENT TO CONTRACT NO. DA-3668 WITH M. ARTHUR GENSLER JR. & ASSOCIATES TO PROVIDE COMPLETE ENGINEERING DESIGN FOR THE PROJECT ENTITLED "SECURITY PROGRAM – IN-LINE BAGGAGE SCREENING

ITEM 11. APPROVE THE THIRD AMENDMENT TO CONTRACT NO. DA-3672 WITH CH2MHILL, INC. TO PROVIDE COMPLETE ENGINEERING DESIGN FOR THE PROJECT ENTITLED "SECURITY PROGRAM – IN-LINE BAGGAGE SCREENING SYSTEMS" AT ONTARIO INTERNATIONAL AIRPORT

ITEM 12. APPROVE THE FIFTH AMENDMENT TO CONTRACT NO. DA-3334 WITH LEO A. DALY COMPANY TO PROVIDE DESIGN AND CONSTRUCTION ADMINISTRATION SERVICES FOR AN IN-LINE BAGGAGE SCREENING SYSTEM AT TOM BRADLEY INTERNATIONAL TERMINAL (TBIT) UNDER THE PROJECT ENTITLED "TBIT INTERIOR IMPROVEMENTS" AT LOS ANGELES INTERNATIONAL AIRPORT

ITEMS 10, 11,
AND 12. Cont'd.

Interim Executive Director Day requested these items be amended to add retention clauses to assure quality and performance and liquidated damages to assure a timely performance to all three of these contracts.

Commissioner Llorens asked how is this design going to work with Alternative D? Kim Day responded--consideration was given to Alternative D and that all equipment is modular and that a majority is reusable should plans be changed. But, she didn't anticipate having to move any equipment.

Commissioner Weil asked how staff is able to measure the documents submitted as being highly complete or high quality? Kim Day responded that the drawings are coordinated and constructible. The Construction Manager will review the drawings as well as LAWA Engineering. Commissioner Weil requested to view the liquidated damages and retention clauses after the City Attorney drafts them. Staff responded affirmatively.

Commissioner Petersen moved the amendment to Items 10, 11 and 12 to add retention clauses and liquidated damage language to these agreements, seconded by Commissioner Weil and it was unanimously adopted.

ITEM 13. AUTHORIZE THE EXECUTIVE DIRECTOR TO PREPARE AND RELEASE A REQUEST FOR PROPOSAL (RFP) AND NEGOTIATE A CONTRACT FOR PROFESSIONAL SERVICES FOR THE PROJECT ENTITLED "LAX MASTER PLAN ADVANCED PLANNING_-PROGRAM AND DESIGN CRITERIA DEVELOPMENT"

Interim Executive Director Day requested the report be amended to add the words with significant roles, after-- Per LAWA policy, consultants-- and the rest of the sentence remain unchanged.

Commissioner Llorens asked whom staff considered major players? Ms. Day stated the prime-contractors, but that a review of the contractual percentages needed to be done in order to determine the other significant players, and after this is done she will present the findings to the Board.

Commissioner Weil recommended the amendment that Ms. Day suggested be changed to-- Per LAWA policy, consultants with responsibility for substantial portions of the work (rest of sentence unchanged).

Commissioner Llorens inquired how the knowledge the major players (contractors) had would be transitioned to the new players (contractors)? Commissioner Weil added clarification by inquiring if and when we have contracts where we anticipate having one set of experts at one point and one set of experts at another, does the initial set of experts have an obligation to reasonably cooperate with the transfer, and then does the second set assume as part of the contract, on that company's watch, the cost of getting "up to speed?"

Jim Ritchie, Deputy Executive Director of Long-Range Planning, affirmed that Interim Executive Director Day had said that the consultant contractors would transition with the existing team. He also expects that LAWA staff likewise is a component to make the transition with the existing consultant team.

Commissioner Weil added that a third cause would be if we didn't get the cooperation? That the contracting party would not be a welcomed contracting party in the future, and we expect people to cooperate and act reasonable.

Cont'd.

ITEM 13. Cont'd.

Commissioner Petersen moved the amended language, as again amended by Commissioner Weil to state: Per LAWA policy, consultants with responsibility for substantial portions of the work on the Master Plan EIS/EIR are precluded from proposing on, and thus possibly securing, advanced planning work with respect to Alternative D project components, seconded by Commissioner Levine, and it was unanimously adopted.

President Stein requested items 2, 6, 9 and 14 be deferred.

oOo

COMMENTS FROM THE PUBLIC

The Board received one comment from Joseph Geber.

oOo

At this time, 9:20 a.m., the Board continued the Meeting in Closed Session for conference with legal counsel to discuss and take action regarding the following:

PRESENT: Commissioners Levine, Llorens, Petersen, Weil and President Stein

CLOSED SESSION -- THE BOARD MAY MEET IN CLOSED SESSION ON ANY SUBJECT PERMITTED BY LAW FOR CLOSED SESSION PURPOSES. THE FOLLOWING ITEMS ARE FOR DISCUSSION AND POSSIBLE ACTION:

CONFERENCE WITH LEGAL COUNSEL - PENDING LITIGATION (GOV. CODE SECTION 54956.9(b)(3)(c):

RESOLUTION NO. 22150

ACTION RE: HUMMINGBIRD, USA, INC. CLAIM FOR DAMAGES

Motion of approval was made by Commissioner Petersen, seconded by Commissioner Weil and it was unanimously adopted.

At this time, 9:25 a.m., the Board reconvened the Meeting in Special Session and the City Attorney reported that the Board took action on the above-mentioned item during Closed Session.

SUBJECT:

AUTHORIZATION FOR THE EXECUTIVE DIRECTOR TO PREPARE AND RELEASE A REQUEST FOR PROPOSAL (RFP), AND NEGOTIATE A CONTRACT FOR PROFESSIONAL SERVICES FOR THE PROJECT ENTITLED "LAX MASTER PLAN ADVANCED PLANNING – PROGRAM & DESIGN CRITERIA DEVELOPMENT".

RECOMMENDATION:

Management RECOMMENDS that the Board of Airport Commissioners:

1. ADOPT the staff report.
2. DETERMINE that this action is exempt from the California Environmental Quality Act pursuant to Article II, Section 2(d) of the Los Angeles City CEQA Guidelines, as amended July 31, 2002.
3. FIND that this work can be performed more economically or feasibly by an independent contractor than by City employees.
4. AUTHORIZE the Executive Director to prepare and release a request for proposal (RFP), and negotiate a contract for professional services for the project entitled "LAX Master Plan Advanced Planning – Program and Design Criteria Development, after approval as to form and legality by the City Attorney.

DISCUSSION:

1. Prior Related Actions

LAX is ranked among the largest airports in the world in terms of aircraft operations, passenger traffic and tons of cargo processed. LAX continues to primarily satisfy regional air transportation demands for domestic and international passengers and air cargo service. LAWA is currently in the final stages of completing the Environmental Impact Statement/ Environmental Impact Report (EIS/EIR) for the LAX Master Plan that will guide the development and modernization at Los Angeles International Airport through the year 2015.

Following the events of September 11, 2001, Los Angeles Mayor James Hahn stated his objective of implementing the enhanced Safety and Security Plan, Alternative D, as soon as possible following the City of Los Angeles approvals and the Federal Aviation Administration's (FAA) Record of Decision (ROD). Master Plan Alternative D reflects the increased concern in airport and aviation security resulting from the events of September 11, 2001 and a decision to limit growth at LAX to 78 million annual passengers (MAP) and 3.1 million annual tons (MAT) cargo. Alternative D also provides for increased passenger capability, more efficient airlines operations and improvements in passenger service, all while improving security. In addition, Alternative D also provides for anticipated new passenger processing requirements and the introduction of the new large aircraft (NLA) in a controlled manner with minimal environmental impact and intrusion on surrounding communities and habitat.

There are two on-going contracts for the LAX Master Plan; DA-3580 (an eighth Amendment was approved by the Board on June 4, 2003 to extend the term and funding until January 31, 2004) with URS Corporation for "Program Management Services for the EIS/EIR and LAX Master Plan" and DA-3581(a ninth Amendment was approved by the Board on June 4, 2003, to extend the term and funding until March 31, 2004) with Camp Dresser & McKee, Inc. for "Environmental Planning Services for the preparation of the LAX Master Plan and EIS/EIR, and for oversight of technical sub-consultants."

2. Current Action

LAWA intends to notify interested firms of the availability of the RFP for advanced planning through advertisements and public notices in appropriate publications. Per LAWA policy, consultants currently working on the Master Plan EIS/EIR are precluded from proposing on, and thus possibly securing, advanced planning work with respect to Alternative D project components. LAWA staff will review and determine qualified consultants and establish a short list. LAWA's panel, consisting of LAWA representatives, will interview qualified consultants and rank them on the criteria set forth in the RFP. After a final ranking, and a list of proposed consultants has been established, LAWA's management will negotiate a contract with the most qualified consultant for complete implementation services which includes, but is not limited to, "advanced programming, advanced planning, program and design criteria development, conceptual phasing plan and schedule, project definition, management services, program controls and conceptual estimates etc." It is Management's intention to return to the Board for authorization to execute and award the contract for a maximum term of three years. No construction will commence prior to obtaining the ROD.

FISCAL IMPACT STATEMENT:

No allocation of funds is required at this time.

STANDARD PROVISIONS:

1. Feasibility and planning studies for possible future action is exempt from the requirements of the California Environmental Quality Act as provided by Article II, Section 2(d) of the Los Angeles City CEQA Guidelines, as amended July 31, 2002.
2. The selected proposer will be subject to the provisions of the Service Contract Worker Retention and/or Living Wage Ordinances in the performance of the contract.
3. Procurement Services has reviewed this item and established a 25 percent combined Minority/Woman Business Enterprise level of participation for this project.
4. The selected proposer must submit an Affirmative Action Plan and comply with the provisions of the Affirmative Action Program.
5. The selected proposer must provide a Business Tax Registration Certificate prior to contract execution.
6. The selected proposer will be required to comply with the provisions of the Child Support Program.
7. The selected proposer will be required to have approved insurance documents on file with Los Angeles World Airports.
8. Pursuant to City Charter Section 1022, the work specified can be performed more economically and feasibly by independent contractors than by City employees.
9. The City Attorney will approve contract as to form.
10. Action taken on this item by the Board of Airport Commissioners will become final pursuant to the provisions of the Los Angeles City Charter Section 245.
11. The successful proposer is subject to the provisions of the Contractor Responsibility Program.

Spending OKd Before LAX Plan Approved

The airport panel chief says design work on Hahn's proposal, costing up to \$2 million a month, must start now to avoid future delays.

By Jennifer Oldham
Times Staff Writer

September 3, 2003

Although the City Council and Federal Aviation Administration have yet to review Mayor James K. Hahn's \$9-billion modernization plan for Los Angeles International Airport, the city Airport Commission voted Tuesday to begin preliminary design work this fall at a cost of \$1 million to \$2 million a month.

The commission, which is appointed by Hahn, voted 5 to 0 to solicit design proposals on elements of the mayor's proposal, which he said favors safety and security over expansion. The process could double the amount of money the city is spending on planning efforts, without any guarantee that Hahn's plan would be approved, officials said.

"They take on some risk that whatever money is spent would be wasted if they don't go forward with the project," said Richard Marchi, senior vice president of technical and environmental affairs at Airports Council International, a trade group.

The city is spending about \$1 million a month on modernization and has logged about \$116 million in planning costs since Mayor Richard Riordan first proposed reworking LAX about 10 years ago.

Hahn's proposal piggybacks on environmental studies done for Riordan's plan.

The City Council will be able to choose from Riordan's expansion proposals as well as Hahn's alternative when it considers the package, probably in about a year.

Advanced planning efforts approved Tuesday by the commission, however, would focus only on Hahn's proposal.

When the commission hires a firm this fall to start design work, the firm will be asked to iron out the details of each piece of the mayor's plan, such as a passenger check-in center, a consolidated rental car

should stop long enough to really listen to the public discussion still underway. Before approving the blueprints, Hahn needs much better consensus on security, of course, but also on cost and capacity in this post-9/11 world.

Council Members Attempt to Cut Speed of LAX Work

Seven on panel oppose soliciting design plans before Mayor Hahn's modernization proposal is reviewed by the city and the FAA.

By Jennifer Oldham
 Times Staff Writer

September 6, 2003

Members of the City Council moved on Friday to block the Airport Commission's fast-track approach to modernizing Los Angeles International Airport, insisting that design work wait until after the plan has been approved.

The Airport Commission voted earlier in the week to solicit design proposals on elements of Mayor James K. Hahn's \$9-billion LAX modernization plan, at a cost of \$1 million to \$2 million a month, even before the plan is reviewed by the City Council and the Federal Aviation Administration. The panel expected to hire a firm this fall.

Council members said Friday that it would be premature to spend money on design work without a guarantee that the plan would be approved.

"A fast-track effort is appropriate and more widely used in non-controversial issues that require little public input and relatively little detailed technical review," wrote Councilwoman Cindy Miscikowski in a motion signed by six of her colleagues. "It is also a tool when overwhelming consensus exists on a proposal, which is clearly not the case on this issue."

Hahn is trying to convince skeptics, including the airlines, residents and lawmakers, that his plan is the best way to modernize the 75-year-old airport. Miscikowski's motion, which the council will discuss on Friday, calls on the commission to delay preliminary design work until a project is in place.

The mayor's office asked the council to reconsider its position and said that adding more details to Hahn's plan would help answer questions posed by skeptics.

"The federal government agrees with the mayor that we want to see safety and security enhancements made at LAX as soon as possible," said Deputy Mayor Julie Wong. "That's why they put LAX as one of a handful of projects they're paying special attention to. We want to make sure on our end that we're fully prepared to implement the master plan when it's passed, which is why we would like to see advanced planning."

facility and an intermodal transportation center.

For example, the firm will be charged with figuring out the specific route that a proposed people-mover would take, how it would enter the proposed check-in center — designated for a neighborhood known as Manchester Square — and at what elevation it would arrive there, said Kim Day, interim executive director for the city's airport agency.

The commission's move was criticized by skeptics who are concerned about the cost of the mayor's plan and who believe that the project would provide no discernible benefit for the local economy beyond short-term jobs created during construction.

"I think committing to spend money on detailed planning when [environmental reports] have raised numerous questions is premature," said Councilwoman Cindy Miscikowski.

"This has not been approved, and they should be cautious about spending money until they know these things will be done," she said.

Airport Commission President Ted Stein said it is necessary to begin nailing down details in the mayor's plan now so that the city won't have to wait several years for consultants to draft construction documents once the project is approved.

EDITORIAL

LAX Plan: What's the Rush?

advertisement

September 12, 2003

The deceptively bureaucratic-looking motion on today's City Council agenda does not commit the council in any way on Mayor James K. Hahn's \$9-billion modernization plan for Los Angeles International Airport. But it would block his effort to speed the plan through, sending the right message to the mayor to slow down and get the remodeling right.

Last week the city Airport Commission, whose members Hahn appoints, voted to hire a consultant to begin nailing down details of the airport plan, such as determining the exact route and elevation of a proposed people-mover. Just one problem: The plan has yet to be approved by the council or the Federal Aviation Administration.

Getting a jump on the design minutiae is not that unusual for such a big public works project, as long as there is general agreement that it will win approval. In this case, that's far from clear.

Former Mayor Richard Riordan's \$12-billion expansion plan stalled three years ago, fought to a standstill by airport neighbors. When he ran for mayor, Hahn, eager for this block of votes, signed a pledge to hold LAX to no more than the 78.9 million passengers a year that planners say the aging airport could accommodate now. (About 56 million used LAX in 2002, down from 67 million in 2000, the peak year before the 2001 terrorist attacks sent air travel into a tailspin.)

After the Sept. 11 hijackings, Hahn called for reconfiguring LAX to make it more secure. Who could argue with that? Plenty of people, it turned out, once the actual plan was unveiled this summer.

What was expected to be a scaled-back remodel had morphed into one of the most expensive public works projects in the country. And the \$9-billion price tag that Hahn cites does not, according to a Times analysis, take into account numerous costs, such as moving 6,000 residents out of a Manchester Square neighborhood intended for a remote passenger check-in center. That huge and probably still growing price would cover a plan that accommodates no more passengers than the current design and therefore does not increase the airport's contribution to the region's economy.

Some of the critics of the Riordan plan see Hahn's as a stealth expansion. Those who take the mayor at his word wonder why his plan costs so much if it doesn't add capacity. There is not even consensus on whether its security measures — the plan's selling point — reflect the best approach.

Hahn and Airport Commission President Ted Stein claim that the design consultant they want to hire at \$1 million a month would answer these questions. But shouldn't LAX's old consulting firm, to which the city has already paid more than \$100 million for planning, be able to do that? Better yet, the mayor

Council Allows Delayed Design Work on LAX Plan

By Jennifer Oldham
Times Staff Writer

September 17, 2003

The Los Angeles City Council decided Tuesday not to block fast-track design work on Mayor James K. Hahn's airport modernization plan after receiving assurances from the mayor that the work would not begin until early next year.

The effect of the decision is a compromise: Officials will not wait for formal approval of Hahn's \$9-billion proposal to update Los Angeles International Airport, but the additional design work, at a cost of \$1 million to \$2 million a month, will be postponed for several months.

Councilwoman Cindy Miscikowski drafted a motion earlier this month to stop the city's Airport Commission from soliciting preliminary design proposals on Hahn's plan before it is reviewed by the council and the Federal Aviation Administration next fall. Six other council members signed Miscikowski's motion, which was viewed by many as an early referendum on Hahn's LAX plan.

Ferocious lobbying ensued. Airlines, labor representatives and others who support the mayor's plan attempted to convince City Council members that blocking design work now would cost the city more money in the long run.

"Delays in the start of construction will only add to the total cost of modernizing our international gateway airport," wrote Airport Commission President Ted Stein to council members.

"The cost increase could well be in the hundreds of millions of dollars and the delay in implementation of improvements could extend up to two years."

Airport Commissioner Miguel Contreras, who is the leader of the Los Angeles County Federation of Labor, said he contacted eight council members and urged them to vote against Miscikowski's motion, adding that 49,000 construction jobs depend on approval of Hahn's plan.

Miscikowski sent a letter to her colleagues asking why consultants who are now working on Hahn's plan — and being paid about \$1 million a month — aren't being asked to do preliminary design work. She sent an e-mail to Westchester homeowner groups that encouraged them to speak at a public hearing on her motion last Friday; many obliged, saying that they supported slowing the planning work.

Consequently, when she introduced her motion Tuesday, Miscikowski said she hardly needed to explain what was at stake.

"You've no doubt received more calls, more information and more detail on this motion, I daresay, than you've seen in your time on the council — and many of you have been here a long time," she said.

But many council members said they wouldn't support further delays in a 10-year effort to devise a politically palatable LAX plan. When it became clear that she wouldn't get enough votes, Miscikowski effectively withdrew her motion. She said she wasn't deterred by the loss.

"I think there was more harm done today in their fight over this motion than they gained in terms of victory," Miscikowski said of the Airport Commission and the mayor's office. "I think they heard today from a lot of my colleagues that they don't necessarily agree with the plan and have a lot of questions."

Several council members who signed Miscikowski's motion said they decided not to block the preliminary design work when Hahn offered the compromise.

"No money will be spent on the advanced planning consultant until the contract is negotiated, approved and executed," the mayor wrote to the council last week. He added that he will ask the Airport Commission not to award a contract until after March 1.

Councilman Antonio Villaraigosa said he changed his mind about Miscikowski's motion when the mayor offered to wait to solicit proposals. Other council members agreed, adding that stopping work is not an option when the city has logged about \$116 million in planning costs since Mayor Richard Riordan first proposed reworking LAX 10 years ago.

"It's important that we move forward with this at this time," said Councilman Tony Cardenas. "Even though this has been a very contentious situation, people are dialoguing and trying to come up with a compromise."

RELEASE****MAYOR HAHN UNVEILS NEW SAFETY AND SECURITY
ALTERNATIVE TO LAX MASTER PLAN**

7/2/02

**CONTACT : Hilda Marella
Delgado, Office of the Mayor
(213) 978-0605****Alternative D Map
Safety and Security Alternative Fact Sheet**

(Los Angeles, California – July 2, 2002) Faced with airport overcrowding and the need to build a safer airport, Mayor Jim Hahn today unveiled a new alternative to the LAX master plan that not only addresses the concerns of the surrounding communities, but also meets security demands.

Mayor Hahn, who currently serves as Chair of the Airport Safety and Security Task Force of the U.S. Conference of Mayors, last fall directed the Board of Airport Commissioners to develop an alternative to the master plan that incorporates the latest technologies and design to address safety and security at the airport while still maintaining his pledge to prevent unreasonable growth at LAX.

"In the past ten months, I have worked to develop a new airport configuration, with the emphasis on building an airport that is functional, efficient, safe and secure," stated Mayor Hahn.

"Last October, I directed the Board of Airport Commissioners to work on developing an alternative plan that would raise the level of safety and security, effectively meet the demand for 78 million annual passengers, eliminate the ring road, add no new runways, seek to eliminate runway incursions and mitigate the negative impacts this airport creates to the surrounding community. I am glad to announce today that we are delivering on those promises," Hahn added.

The proposed plan will cost approximately \$9 - \$10 billion and will be done in four phases beginning in 2004. The airport will remain fully operational during construction.

Mary Lou Crocket, a Westchester community activist and former airport commissioner, applauded Mayor Hahn's goals in seeking stakeholders input, including that from the neighboring communities, in an effort to create a consensus behind the plan.

"Clearly staff took the Mayor's vision and designed a strategy that focuses on a single principle: building a state of the art airport for Los Angeles and its travelers," Crocket said. "This plan presents an opportunity to build a secure and convenient LAX that serves a global market, but not at the expense of the surrounding community."

United Airlines also commended Mayor Hahn for his decision to move forward with his plan to modernize Los Angeles International Airport.

"United looks forward to active and direct involvement in the refining of this project so as to provide our customers with greater convenience and efficiencies, and to ensure that LAX continues to occupy its rightful position as the leading economic engine of this area," said Mark Liberman, United Airlines Vice President-Western Region.

The reconfiguration of LAX is critical to the regional economy. Worldwide, LAX ranks third in tons of air cargo handled, with 2.2 millions tons of freight shipped in 2000. LAX also contributes more than 400,000 jobs to the region. Those numbers are expected to multiply with the airport's makeover.

"A key factor is planning for future growth in international airline traffic, especially in accommodating the next generation of long-haul jets," said Jack Kyser, from the Los Angeles Economic Development Corporation. "Our future relies on the international market place. We must make sure that we have the most efficient door to the market, because if we don't there are a lot of other areas that will grab our business."

"The new alternative Mayor Hahn has proposed appears to be a good step in the right direction to modernizing LAX and spreading air traffic throughout Southern California. This plan reflects much of what the community has been calling for at LAX," said Los Angeles County Supervisor Don Knabe, who represents the LAX area.

Hahn's plan for LAX also received support from the local Chapter of the Association of Flight Attendants.

"The Mayor's alternative for LAX looks to the future of the aviation industry and has provided for the space needed to provide a secure structure for employee parking, which includes a separate security checkpoint for all employees. This will streamline the procedure for those who work here and, most importantly, standardize it," said Holly Hightower, Secretary Treasurer for the Los Angeles Chapter of the Association of Flight Attendants.

NEWS RELEASE

MAYOR JIM HAHN RELEASES ENVIRONMENTAL ANALYSIS AND DETAILS OF HIS ENHANCED SAFETY & SECURITY ALTERNATIVE FOR LOS ANGELES INTERNATIONAL AIRPORT MASTER PLAN

7/9/03

CONTACT : Hilda Marella Delgado
Office of the Mayor
(213) 978-0605

(Los Angeles, California -- July 9, 2003) Delivering on his pledge to make Los Angeles International Airport (LAX) the safest and most secure airport in America, Mayor Jim Hahn today announced the release of the environmental analysis and further details of his plan to modernize LAX as an integral part of a Southern California regional air transportation system.

"The goal of creating this Enhanced Safety and Security Master Plan is to modernize LAX to protect one of Los Angeles' key economic engines," Mayor Hahn said. "At the same time, the plan addresses community interests and concerns by designing the facility to serve only LAX's fair share of the total regional air service market."

Mayor Hahn was joined by representatives of business, labor, airlines, government and the community at the announcement of the public review and comment period for the Supplement to the Draft Environmental Impact Statement/Environmental Impact Report (SDEIS/EIR), including his LAX Enhanced Safety and Security Master Plan (Alternative D).

Mayor Hahn announced that the public review period on the LAX Master Plan will be held through August 25, 2003. Nine public hearings will be conducted throughout the region between August 11 and August 23. The Master Plan is a joint effort of the City of Los Angeles, Los Angeles World Airports (LAWA) and the Federal Aviation Administration (FAA).

The LAX Master Plan was placed on a federal streamlining list earlier this year to help facilitate the environmental review process at the federal level.

Mayor Hahn, who serves as the Chair of the U.S. Conference of Mayors Airport Safety and Security Task Force, announced his intention to prepare an alternative to the LAX Master Plan on October 8, 2001. Since then, planners, engineers and environmental consultants have been working with airport officials to further develop the plan and analyze its environmental impact.

Airport officials and Mayor Hahn's staff held more than 100 stakeholder meetings with airline representatives, chambers of commerce, elected officials and community members across the region as the plan evolved, briefing approximately 2,800 people in the last year alone.

"I am looking forward to continue seeking community and stakeholder input in the coming months," said Mayor Jim Hahn. "We are working together to make every effort to keep LAX safe and secure."

The plan designs the future airport to accommodate approximately 78.9 million annual passengers and 3.1 million annual tons of cargo. These traffic volumes are consistent with the goals established in the Southern California Association of Governments 2001 Regional Transportation Plan to promote growth of underutilized airports in outlying areas and to achieve a more decentralized distribution of future air traffic around the region.

Mayor Hahn said the approximately \$9-billion plan would be designed and constructed in phases over an 11-year period beginning in late 2004. The program would be financed through a combination of airport funding mechanisms, including revenue bonds, grants, concession revenues, Passenger Facility Charges, leases and landing fees. Mayor Hahn pledged that no taxpayer dollars would be expended from the City's General Fund.

The construction of airport improvements suggested in the plan would create nearly 49,000 direct construction-related jobs, pumping millions of dollars into the local economy. Mayor Hahn said it would be the largest public works project in America to require Project Labor Agreements (PLA).

The plan addresses four crucial areas: (1) airfield, including runway and taxiway safety improvements; (2) ground access (roadways, transit), automobile parking and rental cars; (3) terminal facilities; and (4) security concerns.

AIRFIELD IMPROVEMENTS

The North and South dual runway complexes would be modified to improve safety through the addition of center parallel taxiways between the runways. The FAA's latest airport design criteria would be applied to all new facilities developed as part of the plan. The North and South airfield usage would be balanced by lengthening the North runways.

These airfield modifications would improve aircraft maneuvering, reduce taxi delay, and increase airfield safety.

GROUND ACCESS

Airport traffic congestion is significantly reduced through new internal airport roads capable of handling passenger volume and expanded direct transit access, as well as proposed mitigation measures calling for direct freeway access.

Alternative D uses the area bounded by Aviation Blvd., Arbor Vitae St., La Cienega Blvd., and Imperial Hwy, as a comprehensive on-airport access area. This area would provide access to the new Ground Transportation Center and Intermodal Transportation Center, and add 36-lane miles of new airport access roads to improve the flow of traffic. Proposed mitigation measures would provide direct connection from the I-405 and I-105 Freeways with grade-separated roadways into the new internal airport roadway system.

The development of a Consolidated Rental Car Facility further reduces airport area traffic congestion. Each of these new ground access facilities would be connected to the airport terminal area by an Automated People Mover System. The automated people mover trains would operate to the Central Terminal Area from stations at each of the nodal points with an average 2-minute frequency.

- ***Ground Transportation Center (GTC)***

The GTC is proposed as the pick-up and drop-off place for LAX travelers. It would replace the curbside drop-off area in the Central Terminal Area (CTA). The GTC would have eight separate 1400-foot long curbsides connecting arrival and departing passengers to two separate and redundant people mover train stations. The curbsides would be identified through electronic signage designating airline and function. Curbside check-in would be available at the departing curbs for those needing or desiring this service.

Hourly structural parking would be available adjacent to the train stations to encourage greeters and well-wishers to stay with or meet passengers in the CTA. The GTC would also provide 7,500 structural parking spaces for long- and short-term use.

Airport security screening of passengers and baggage would be conducted at the GTC. The facility would be designed to accommodate security mechanisms such as limitations on the size and type of vehicles allowed at the curbs and in the parking garages, uniformed and plain-clothes officers, canine patrol units, advanced technology devices and behavioral observation. The GTC would have the space and flexibility to normalize airport operations even while responding to heightened security needs.

- ***Intermodal Transportation Center (ITC)***

The ITC would be the LAX connecting point for the Metro Rail Green Line light rail, regional transit buses, and future Metropolitan Transit Authority (MTA) rapid buses. The ITC would have a direct connection by a power walkway to the Green Line light rail station at Aviation Blvd. and Imperial Highway.

The ITC would also provide 9,100 structural parking spaces. An adjacent lot would offer 5,500 surface parking spaces. Structural parking would be for daily (less than seven days) business travelers and surface parking would likely be used by long-term and weekly travelers. The ITC would be conveniently connected to the CTA by the airport Automated People Mover System.

The same airport security screening used in the GTC would also be employed at the ITC.

- **Consolidated Rental Car Facility (RAC)**
All on-airport rental car companies would have their facilities in a single, consolidated location. Ready and return structural spaces would abut a people mover station to facilitate easy roll-on or roll-off, non-stop service to the CTA. Rental car quick turnaround service areas, personnel offices, maintenance facilities and car storage lots would radiate from the ready and return spaces for maximum rental car company efficiency. The consolidation into one rental car center would facilitate directional signage for RAC customers to and from adjacent interstate highways and local streets.

The same airport security screening used in the GTC and ITC would also be employed at the RAC prior to passengers boarding the Automated People Mover System.

- **Automated People Mover System (APM)**
The new facilities would be built with People Mover Stations that service the CTA. Service would be available every 2 minutes with an average wait of just one minute. The APM would provide non-stop service from the GTC to the CTA in approximately 5 minutes. Service from the ITC to the CTA, with just one stop at the RAC, would be less than 8 minutes.

Each APM station would have two tracks and be designed in a flow-through manner, whereby entering and exiting passengers use opposite sides of the car. The People Mover trains would be designed to easily and efficiently accept both roll-on luggage and baggage. The APM would operate on elevated structures so as not to interfere with existing roadways.

REDEVELOPED CENTRAL TERMINAL AREA (CTA)

Today, LAX serves its passengers through a combination of less than 4 million square feet of terminal landside and airside buildings. This well-used space is inadequate by today's standards and prevents the flexibility to respond to changing security needs.

The LAX Master Plan proposes to bring LAX's terminal facilities into the 21st Century by creating a new central landside terminal in the space now occupied by the CTA parking structures. Passenger and baggage screening conducted by the Transportation Security Administration (TSA) would take place in this facility and in close proximity to the aircraft gate areas. This new passenger terminal would be connected to a new North Linear Concourse replacing Terminals 1, 2, 3 and the north side of the Tom Bradley International Terminal (TBIT). The Bradley Terminal would be redesigned to add a new passenger concourse and aircraft gate area on its existing west face. A new Satellite Concourse would be constructed west of TBIT and would be connected to the main terminal by a secure underground people mover. Existing Terminals 4, 5, 6, 7 and 8 would be refurbished, as necessary, and connected to the new main terminal building.

The new terminal and passenger concourses would occupy more than 6.5 million square feet of space and bring LAX's passenger facilities up to today's international and domestic standards for all functional spaces.

NORMALIZED OPERATIONS UNDER HEIGHTENED SECURITY

The focus of Mayor Hahn's plan for LAX is to normalize passenger operations under any security circumstance. Meeting security requirements at LAX today are expensive and disruptive to the daily movement of people and goods through the airport and on local area streets. The Master Plan improvements would create the space and separation needed to balance the needs of airport users with the facilities, systems and tactics necessary to protect lives and airport infrastructure from those who aim to disrupt and destroy commerce in the U.S. The plan provides the space and flexibility necessary to meet the evolving federal security requirements.

The plan would employ the latest evolving technologies to identify and intercept all threats through checked and carry-on baggage. It would also eliminate the possibility of major disruptions to airport operations by removing all non-essential vehicles from the Central Terminal Area/central processing area of the airport.

A security analysis of the Enhanced Safety and Security Alternative performed by Science Applications International Corporation (SAIC) is included in the Draft Master Plan Addendum. It concludes that Alternative D is "overwhelmingly a better plan for LAX than the No Action/No Project Alternative. The ability of Alternative D to be flexible to meet future security needs is an optimal, forward thinking design." SAIC is the nation's largest employee-owned research and engineering company, providing information technology, systems integration and eSolutions to commercial and government customers.

The SDEIS/EIR and Draft Master Plan Addendum is available to the public for review in a variety of ways. Copies are available in 50 local and regional libraries, at the LAX Master Plan Public Reading Room located at the Imperial Terminal/Flight Path Learning Center at 6661 Imperial Highway and other locations across the region. The documents can also be viewed in their entirety on the Internet at www.laxmasterplan.org or purchased in various formats, including CD-ROM, by contacting Printco Graphics at (323) 727-6668.

Following the conclusion of the public comment period, the FAA, airport staff and its consultants will respond to comments and make any needed revisions based on the public input. The result will be a Final Environmental Impact Statement/Environmental Impact Report that will be forwarded to the Board of Airport Commissioners, the Los Angeles City Planning Commission, and then the Los Angeles City Council for review and action. Following City approvals, the plan will be forwarded to the FAA for coordination of final review and issuance of a Record of Decision.

Re: Draft and Supplemental Draft Environmental Impact Report/Environmental Impact Statement, Los Angeles International Airport Proposed Master Plan and Master Plan Addendum - Comments of the City of Inglewood

Dear Mr. Ritchie and Mr. Kessler:

The following constitute the comments of the City of Inglewood ("Inglewood") concerning the Draft ("DEIR") and Supplemental Draft Environmental Impact Report/Environmental Impact Statement ("SEIR") for the Los Angeles International Airport ("LAX") Master Plan ("Master Plan") and Master Plan Addendum ("Addendum") (together "Project"), submitted pursuant to the requirements of the California Environmental Quality Act, *Public Resources Code* § 21000, *et seq.*, ("CEQA"), its implementing Guidelines, 14 Cal.Code Regs. § 15000, *et seq.* ("CEQA Guidelines") and the National Environmental Policy Act, 42 U.S.C. § 4321, *et seq.*, ("NEPA").

It should be noted at the outset that the body of this letter emphasizes evaluation of new Alternative D as set forth in the SEIR. However, LAX has chosen a format that purports to integrate the analysis of Alternative D into the platform of the original DEIR which is predicated on analysis of Alternatives A-C. While Inglewood believes this format is not optimal in achieving the goal of informing the public and decision makers of the Project's potential impacts, as set forth below, it has attached comments specific to the analyses of Alternatives A through C, as contained in the DEIR, to the extent they remain applicable, as Attachment 1 to this letter. If

SAL00016

should be further noted that issues raised in Attachment 1 with regard to the analytic adequacy of the DEIR with respect to Alternatives A through C may impact the adequacy of the SEIR's analysis of Alternative D. With that caveat, the issues raised with respect to Alternative D fall generally into six categories:

(I) The SEIR's Project definition is improperly attenuated in that: (a) its baseline for analysis is 1996, almost 10 years before scheduled commencement of Project construction. While arguably reflective of physical environmental conditions in the vicinity of the Project when the Notice of Preparation ("NOP") for the DEIR was published in 1997, a 1996 baseline cannot faithfully represent environmental conditions 10 years later; and (b) the SEIR's purported 15 year term, from the year 2000 to the year 2015, does not take into account the four to five year delay in Project implementation from 2001 to at least 2005-6, and, thus, leaves the final five (5) years of the 15-year term of Project implementation, from 2015 to 2020, and the environmental impacts that may arise during those years, unanalyzed;

(II) Alternative D does not represent a meaningful constraint on capacity because it does not consider the capacity enhancing capability of new large aircraft or the Project's airfield reconfiguration designed to accommodate them;

(III) As a result, the SEIR's noise analysis fails to fully reveal the Project's aircraft and traffic noise impacts on homes and schools, the vast bulk of which fall on Inglewood, or to provide adequate measures to mitigate those impacts;

(IV) The SEIR's air quality methodology and resulting analysis does not adequately portray the emissions impacts of construction vehicles, aircraft and ancillary Ground Support Equipment ("GSE") or truck traffic associated with the Project;

(V) The SEIR's traffic analysis understates the Project's traffic impacts;

(VI) The SEIR's proforma discussion of environmental justice does not fully address the skewed distribution of the Project's impacts which fall almost entirely upon the minority/low income citizens of Inglewood, or offer adequate measures to avoid, minimize or mitigate the maldistribution of Project impacts.

I. THE SEIR'S PROJECT DEFINITION IS INCOMPLETE.

The SEIR's Project definition is improperly circumscribed by: (1) the utilization of the vehicle of a "supplemental" EIR, where a complete new EIR, encompassing Alternatives A through D would have been appropriate; (2) the utilization of a 1996 baseline, dating back seven years from the publication of the SEIR, where data indicates that the correct baseline would have been the full year 2001; and (3) the utilization of the years 2000 to 2015 as the 15-year term of

the Project, even though the Project, under the most optimistic circumstances, is not scheduled to begin until 2005 and, thus, a fifteen year Project term will end in the year 2020, leaving the environmental impacts of the Project arising during the last five years of the Project term, from 2015 to 2020, unanalyzed.

A. The SEIR Improperly Attenuates Analysis of the "Whole" Project.

A "project" for CEQA purposes, "means the whole of an action, which has the potential for resulting in either a direct physical change to the environment, or a reasonably foreseeable indirect physical change in the environment . . ." CEQA Guidelines § 15378(a). "Project" is "given a broad interpretation so as to maximize protection of the environment." See, e.g., *McQueen v. Board of Directors of the Midpeninsula Regional Open Space District*, 202 Cal.App.3d 1136, 1143 (1988). "In general, the lead agency must fully analyze each "project" in a single environmental review document." *Remy, Michael, Guide to the California Environmental Quality Act*, 10th Ed.1999, p. 75. "Thus, in performing its analysis, the agency should not split a project into two or more segments", *Id.*, thus insuring "that environmental considerations do not become submerged by chopping a large project into many little ones . . ." *Burbank-Glendale-Pasadena Airport Authority v. Hensler*, 233 Cal.App.3d 577, 592 (1991).

That dissection of a large project into several smaller ones is, however, precisely what seems to have happened here. Although the SEIR purports to relate Alternative D to DEIR Alternatives A through C, in reality the two documents are not directly comparable. The principal goal of the DEIR is capacity expansion and elimination of delay. [". . . [I]f LAX does not increase capacity to accommodate some of the projected increase in demand for air travel services, the demand will be met by other airports in the region or elsewhere in the Western United States." The principal goals of Alternative D are, however, very different, *i.e.*, (1) to enhance the safety and security at LAX for users and to protect the airport infrastructure; (2) to encourage the development and use of regional airports to serve local demand by constraining the facility capacity to approximately the same aviation activity levels identified in the no action/no project alternative; (3) to maintain LAX as the international gateway to Southern California; and (4) to mitigate the environmental impacts of LAX's continued operations, SEIR, Section 2, pp. 2-1, 2.

Even though the SEIR maintains that "purpose and need for the LAX Master Plan has not changed since the publication of the DEIR", Executive Summary, p. ES-1, it is clear that adequate analysis of the two sets of alternatives involves different data, methodology and assumptions. As a consequence of the failure to incorporate the analyses of all alternatives into a single document, structured by the same goals, assumptions and methodologies, the conclusions concerning Alternative D's relationship to the other alternatives, as well as to the environment, are suspect at the outset.

Moreover, the SEIR exceeds the proper scope of a supplement as set forth in the CEQA Guidelines. A supplement only “augments a previously certified EIR”, CEQA Guidelines § 15163, Discussion, and only where “minor additions or changes would be necessary to make the previous EIR adequately apply to the project in the changed situation.” CEQA Guidelines § 15163(a)(2). Neither of these conditions exists here. The DEIR was never certified. Further, the changes to the Master Plan contained in the SEIR are far from minor. In fact, they constitute a new “preferred alternative”, supported by new goals, objectives, methodological approaches, and data, as well as resulting comparisons and ultimate conclusions.

The legislature and the public resources agency charged with CEQA’s implementation have taken the position that, prior to ultimate certification, a single project must be analyzed in a single comprehensive document. The rationale for this position becomes clear with reference to the SEIR. The isolation of a single alternative, Alternative D, and the consequent welter of cross-references to the previous DEIR, a two year old document, its technical reports and appendices, as well as to the SEIR, its technical reports and appendices, is a nearly insurmountable challenge to the public and to decision makers, even if the analytic framework of the DEIR and SEIR were comparable, thus defeating CEQA’s principal goals of “informed decision-making and informed public participation.” *Save Our Peninsula Committee v. Monterey County Board of Supervisors*, 87 Cal.App.4th 99, 118 (2001).

B. The Use of the Years 1996 and 2015 as the Project’s Temporal Parameters is, in Practical Terms, Inappropriate.

Despite the distinct justification and framework of analysis for Alternative D, the SEIR links Alternative D to the DEIR through the use of the same 1996 environmental baseline and 2015 Project end date. While the 1997 date for publication of the NOP (or 1996, the last full year of data before publication) theoretically constitutes the correct environmental baseline, CEQA Guidelines § 15125(a),¹ it does not in this case, for at least two reasons. First, the 1996 baseline used in the DEIR does not accurately reflect the physical conditions in the vicinity of the Project even at the time of the publication of the NOP in July 1997 (see Attachment 1, pp. 3-6). Second, even if 1996 did accurately reflect conditions applicable to the DEIR, it does not do so where, as here, a complete new comprehensive EIR containing equivalent analyses of all alternatives is required. The new EIR would have required publication of an NOP sometime after the year 2001, when the DEIR was originally circulated. Thus the years 2001 or 2002, the

¹ CEQA Guidelines § 15125 states, in pertinent part: “An EIR must include a description of the physical and environmental conditions in the vicinity of the project, as they exist at the time the notice of preparation is published, or if no notice of preparation is published, at the time environmental analysis is commenced, from both a local and regional perspective. This environmental setting will normally constitute the baseline physical conditions by which a lead agency determines whether an impact is significant.” CEQA Guidelines § 15125(a).

likely last full years of data before the publication of the new EIR, would have been the appropriate base years for the analysis contained in the SEIR.

Nevertheless, the SEIR avoids the use of 2001/2002 by introducing a year 2000 baseline “for informational purposes only”, predicated on “the most recent normal year for which a complete data set is available.” SEIR, § 3, p. 3-5. The rationale behind the choice of the year 2000 was apparently that, due to the terrorist attacks of September, 2001, “2001 is an anomalous year that would be inappropriate to use for a comparison to the Draft EIS/EIR’s baseline year.” SEIR § 3.2.1, p. 3-5, and “similarly, aviation activity in 2002 is also considered to be an anomalous year due to the effects of September 11, 2001.” SEIR, § 3.2.1, p. 3-5.

Neither the SEIR’s conclusions nor its rationale are convincing. SEIR, App. S-B acknowledges that, with respect to the year 2001 “the typical month for the design day schedule (August) would be unaffected by September 11, 2001.” App. S-B, p. 1 [emphasis added]. Nevertheless, the SEIR further opines “the ratio of peak month activity to annual activity is exceptionally high, due to the overwhelming fourth quarter decline in activity,” App. S-B, p. 2, although the SEIR contains no data to support that contention. However, review of OPSNET statistics for the years 1996 through 2002 reveals that operations for the full year 2001 at LAX declined by only 50,000, to 738,679 from the seven year high of 783,684 reached in 2000. The data also demonstrates natural annual fluctuations of almost 20,000 operations between 1996 (approximately 763,000 operations) and 2000 (approximately 783,000 operations). Thus, use of 2001, with requisite caveats, would have constituted at least as accurate a picture of the environmental circumstances in the vicinity of the Project as did the year 1996, seven years in advance of the publication of the SEIR.

The practical impact of utilizing the year 2001, rather than 1996, as a base year, is manifest. As there were fewer operations in 2001, and, thus, potentially fewer environmental impacts from them, a comparison with the Project years would have resulted in greater apparent impacts from the Project, than when compared to 1996, with a larger number of operations and concomitant impacts.

Finally, the use of the year 2015 as the end point of the Project is confounding at best. The SEIR’s purpose and need statement includes the need to “respond to local and regional demand for air transportation during the period 2000 to 2015”. SEIR, p. ES-1. From that statement, it can be reasonably deduced that LAX looks to a 15 year Project period. The problem is that the Project will not now commence construction, let alone full implementation, until in or after 2005. This would bring the end point of the Project period to the year 2020. 2020 is, however, outside the DEIR’s, as well as the SEIR’s, scope of analysis. In other words, the SEIR appears to leave the environmental impacts which may arise during the last five years of the Project’s implementation entirely unevaluated.

II. ALTERNATIVE D DOES NOT REPRESENT A MEANINGFUL CONSTRAINT ON CAPACITY, AND, THUS, WILL CAUSE IMPACTS IN EXCESS OF THOSE ANTICIPATED FROM THE "NO PROJECT" ALTERNATIVE.

One of the SEIR's stated goals is to "encourage the development and use of regional airports to serve local demand by constraining the facility capacity at LAX to approximately the same aviation activity levels identified in the no action/no project alternative." In support of that goal, the SEIR proposes a purported reduction in the available number of loading gates and spaces from 163 to 153; reduction in the linear feet of terminal frontage; and maintenance of cargo warehouse space at 3.1 million square feet. Despite these changes, the SEIR does not meet its goal of constrained capacity.

A. The New Runway Configuration Encourages Access for New Large Aircraft.

First, the reduction in available gates will not meaningfully constrain capacity because of the evolution toward higher utilization of New Large Aircraft ("NLA"), including the A380. With increasing use of NLAs, the airport will be able to accomplish more throughput with fewer gates, although of a larger size. The close to doubling in terminal capacity as between the 1996 baseline and Alternative D (from 3,997,000 square feet to 6,550,000 square feet) will also serve to accommodate the apparent projected increase in passengers resulting from introduction of NLA's.

NLAs are not however included in the projected fleet mix for the Project (SEIR, App. SC-1, Table S7), although it is apparent that the real aim of the Project is to accommodate them. The reconstruction and separation of Runways 7R/25L and 7L/25R in the south complex, and the addition of parallel taxiways (SEIR, Section 3, p. 3-48), as well as the ultimate extension of Runway 6R/24L to 1,280 feet to the east, to a total length of 11,700 feet and the extension of Runway 6L/24R 1,495 feet to the west, for a total length of 10,420 feet (SEIR, Section 3, p. 3-41) confirm that conclusion.

B. The Separation of Runways and Additional Taxiways Will Encourage Increased Capacity for Conventional Aircraft.

Second, even without NLAs, capacity would increase. Staggered runway ends (SEIR, Figure S3-8), permits simultaneous arrivals and departures in Visual Flight Rule (clear) weather, as do increased runway separations. The construction of two parallel taxiways between existing sets of runways will also allow an increase in the number of operations the airport can accommodate. Aircraft will be able to land with minimal separation and will be able to hold on taxiways between arrival and departure runways. Aircraft will then be able to land on one parallel runway and depart on the other without interruption. Multiple aircraft can be held between runways crossed to the terminal when there is no departure demand. This changed

configuration is a striking contrast to today's situation where there is not room to hold multiple smaller aircraft between the runways. If an aircraft is holding at a runway exit, the landing aircraft must now proceed to another exit. This requires increased separation between arrivals as there is not sufficient room to hold the aircraft exiting the runways.

Finally, the proposed limitation on increase in cargo handling facilities to 3.1 million square feet, as a means to control capacity, is entirely beside the point. Many cargo carriers at LAX are in the business of "same day" delivery, requiring fast turn around, but no warehousing. Where warehousing is required, off-site warehousing is available.

C. Alternative D Does Not Appear to Materially Further the Twin Goals of "Safety and Security".

In stark contrast to the SEIR's unstated goal of capacity increase, its stated goals of increased safety and security are elusive. With respect to the alleged Project safety goal of remedying runway incursions, obviously the proposed runway taxiway configuration will help. In the last analysis, however, six billion dollars is a steep price to pay, where significant improvements could be achieved by better airport signage, increased controller and pilot education, and strict enforcement of regulations and relevant provisions of operations handbooks.

With respect to security, Alternative D is an anachronism. By the time it is completed in 2015 or after, the world situation and/or technological progress will likely have rendered the security rationale for restructuring whole terminals and parking structures as well as freeway access to make them even more remote from aircraft and difficult for passengers to access, obsolete. While the goal is noble, Alternative D vastly exceeds current security requirements, developed and administered by the Transportation Security Agency, which the SEIR acknowledges are currently being met at LAX. On the other hand, the SEIR fails to address security issues such as: (1) the potential threat directly posed by airport employees and vendors who cannot, by virtue of their jobs, be funneled through the GTC; (2) the near term additional Federal security requirements such as the requirement for screening of cargo; and (3) the potential for attack on the GTC itself, where thousands of passengers will be concentrated, instead of disbursed, as they are now, through a number of terminals.

In summary, the final goal of Alternative D, to make LAX an international hub, is the dominant one, although somewhat inconsistent with Alternative D's other goals, because it can only be accomplished through the significant increases in capacity brought about by the reconfiguration of the airfield to allow the introduction of NLA capable of carrying large numbers of passengers long distances. Capacity increases are inevitably accompanied by increases in air quality, noise and related impacts. Therefore, the theme that flows throughout the

SEIR, that the characteristics and impacts of Alternative D are more or less the same as those of the "No Project" alternative is, at minimum, an overly optimistic assessment.

III. ALTERNATIVE D'S NOISE IMPACTS ARE, AT BEST, UNVERIFIABLE AND, AT WORST, UNDERSTATED.

Alternative D's noise impacts in general, and on Inglewood specifically, appear significantly understated. As a consequence, the mitigation measures set forth in both SEIR, Sections 4.1, Noise, and 4.2, Land Use, are inadequate to compensate for its impacts.

A. The SEIR Appears Methodologically Flawed.

One of the most notable issues from a methodological perspective is, as set forth above, the absence of the NLA, the A380 aircraft, from the fleet mix from which the noise analysis was derived (see SEIR, App. SC-1, Table S7). If, as set forth above, the NLAs are the principal beneficiaries of Alternative D's proposed reconfiguration of the airfield, their operation should be anticipated from a noise perspective. As it stands, however, Inglewood, and other affected communities, remain in the dark regarding the potential noise impacts of the larger, heavier, and potentially noisier aircraft. And, as Inglewood is the principal recipient of arrival noise, the size and shape of the contour over Inglewood may be materially affected by the omission of the A380 and other NLAs from the Project fleet mix.

The second issue arises out of the bifurcation of the analyses of DEIR Alternatives A through C, from SEIR Alternative D. SEIR App. S-C1 states that the DEIR was prepared with the INM 6.0 model, and the SEIR with the INM 6.0c model. As the two model versions use slightly different databases, it is not possible to ascertain whether the comparisons contained in the SEIR between alternatives are, in fact, accurate.

Similarly the flight track assumptions in the DEIR and SEIR diverge. SEIR, App. SC-1, Exh. S2, contains what purports to be existing flight tracks to the west for the noise analysis of Alternatives A through C, showing multiple turns originating immediately at the ends of the runways. SEIR, App. SC-1, Exhibit S4, however, reveals accurate flight tracks which do not begin to diverge until at or about the shoreline. The use of flight tracks that diverge immediately after takeoff, and prior to the shoreline, results in noise contours artificially expanded to the north and south along departure routes in areas west of the airport. Had the actual flight tracks represented in SEIR, App. SC-1, Table S4 for Alternative D, been used in the DEIR noise analysis of Alternatives A through C, the noise contours to the north and south depicted in the DEIR for Alternatives A through C would have been nearly identical to those in the SEIR for the analysis of Alternative D. As a result, the purported beneficial change to communities north and southwest of the airport from implementation of Alternative D may not exist if the correct

baseline for noise analysis is used. Absent defensible inputs, it is not possible to ascertain with any certainty the integrity of the comparative results of the noise modeling.

Further, the apparent contradictory information set forth in SEIR, App. SC-1 [“Reserve runway 6L/24R for arrival traffic only, during normal operating conditions . . .” See, *e.g.*, § 3, p. 3-42, and Tables S-2 and S-8, which appear to demonstrate the use of both outboard runways for both arrivals and departures at all times of the day (see also Section 3, p. 3-42 [“occasional departures would continue off the outboard runway 6L/24R during peak departing period. . .”], obscures both Alternative D’s capacity enhancing and consequent noise enhancing potential. Departures over Inglewood on Runway 6L/24R at night could substantially change the noise contours in ways not already analyzed or disclosed in the SEIR. In addition, SEIR, App. SC-1, Project 2.1.4, states that a 3 degree glideslope has been assumed for all approaches. While this is the normal default option, the SEIR does not: (1) validate the assumption with use of actual data from LAX operations; or (2) disclose the noise impacts of the 3 degree glideslope, when combined with the extension of Runway 6L/24R over 1,000 feet to the east. A preliminary calculation reveals that the combination may result in aircraft between 125 and 250 feet lower in altitude over Inglewood, with concomitantly higher noise impacts on arrival not disclosed in the SEIR.

The same lack of validation impacts flight track and operations data in several ways. First, SEIR, App. S-C1, Section 2.1, states that the LAX software automatically assigns an aircraft to a flight track and to an INM aircraft type. However, the SEIR is not clear as to whether there any radar tracking data to verify the INM assigned flight tracks, nor is it clear that the aircraft types are being assigned properly (*e.g.*, “light” vs. “heavy” aircraft). Second, SEIR, App. S-C1, Section 2.1.5 states that the average number of aircraft operations by aircraft type and time of day were estimated on proportional basis, using the 85% of operations that were actually monitored by the LAX software. The Appendix does not reveal, however, whether this approach yields data that is consistent with actual operations at the airport. Third, SEIR App. SC-1, Table S-15, which purports to identify the anticipated L-MAX noise levels generated by aircraft operations provides no comparison with the results from noise monitoring stations surrounding LAX to determine the accuracy of the INM model in predicting L-MAX levels.

Fourth, SEIR App. SC-1, Table S14, portrays the aircraft noise analysis results in terms of DNL not CNEL. As DNL is a less stringent measure which omits additional weighting to noise events that occur in the evening hours from 7:00 to 10:00 p.m., a conversion factor must be applied to DNL results in order to accurately portray CNEL impacts. As a consequence, the CNEL impacts identified in SEIR, App. SC-1, Table S20, cannot be corroborated.

Last, and potentially most crucial, SEIR App. SC-1, Section 2.1.7 states that the INM underpredicts the CNEL by 0-3 dB based on noise monitoring around LAX. As the INM model uses SEL values to calculate L_{eq} and CNEL, it may be reasonably concluded that the SEL and L_{eq}

analyses for Alternative D are also underpredicted by the same 0-3dB. Although a deviation of 3 dB CNEL is significant, as alluded to in the SEIR significance criteria used for assessing airport noise impacts, the SEIR contains no attempt to investigate the accuracy of the input data for the INM model for the purpose of calibrating the model to actual measurements at LAX, or verifying the results of the noise analysis.

B. Alternative D Does Not Fully Assess the Noise Impact on Inglewood Schools.

It is above dispute that, in general, the potential impacts of airport noise on children, and particularly children in a learning environment, are of critical importance, not only to the children and their families, but to society as a whole. Of particular importance to Inglewood, however, is that, as set forth in SEIR, App. SC-1, Alternative D will result in 12 additional schools in Inglewood exposed to single event noise levels sufficient to disrupt classes, as compared to noise levels in 1996. Nevertheless, the SEIR disaffirms significant impact from the increased exposure. SEIR Section 4.1.2.1.2, Project 4-11. ["no reliable statistical relationship between the amount of aircraft noise exposure present and the degree of learning difficulty experienced by children at affected schools" has been established.]

The treatment of the noise methodology used to evaluate noise impacts on schools reflects this conclusion. For example, SEIR Section 4.1.2.1.2, states that the peak hour of airport operations during school hours was used to assess the impact of aircraft noise on the schools. While this would be the proper approach (based on the threshold of significance established for the Project), SEIR, App. S-C1 reveals that instead of the peak hour, an average of 8 school hours was used in the analysis.

Moreover, the L_{eq} metric used in SEIR, App. SC-1, Table S33 appears incorrectly calculated. The average L_{eq} for the 8 hour school day in Table S33 is obtained by adding 10 log (3) to the 24 hour L_{eq} calculated by the INM model. The basis for this calculation appears to be that the 8 hour school day is 1/3 of the 24 hour day. However, this methodology is not correct since flights are not evenly distributed throughout the day. The result of the analysis is an average L_{eq} that is too low because most flights at LAX occur during the daytime. It should be further noted that, as set forth above, the model is acknowledged to underpredict L_{eq} values by 0 to 3 dB in any event. This underprediction, as well as the diminution in L_{eq} values caused by averaging were apparently not considered in the analysis or assessment of impact which should have been based on the peak, not average, hour, as acknowledged in SEIR Chapter 4.1.

Finally, while Section 4.1.2.1.2 also states that the "time above" was used as a threshold to evaluate noise impacts on schools, "time above" was not identified as a significance criterion in SEIR, App. S-C1. In fact, as set forth in SEIR Section 4.4.1.1, it is not clear whether the "time above" criterion is cumulative for a school day or for the peak hour, or whether it applies to each individual aircraft event. If it is cumulative, it can take many aircraft disruptions to achieve the 3

second “time above” criterion level used in the SEIR to establish disruption, thus creating an unrealistically high hurdle to the establishment of noise impacts on school populations.

C. Because of the Under Calculation of Noise Impacts, Measures Offered to Mitigate Noise Impacts on Schools are Inadequate.

Just as the analysis of noise impacts on schools is incomplete, so are the mitigation measures to remedy those impacts. Mitigation measures applicable to noise impacts on schools are limited to MM-LU-3 [“conduct study of the relationship between aircraft noise levels and the ability of children to learn”, SEIR Section 5, Project 5-21], and MM-LU-4 [“provide additional sound insulation for schools shown by MM-LU-3 to be significantly impacted by aircraft noise”, SEIR Section 5, Project 5-21 [emphasis added]]. The former involves the conduct of a study to determine if any measurable relationship exists between aircraft noise levels and the ability to learn. The latter is contingent upon the outcome of the former. The proposed measures are both legally and practicably inadequate.

First, it does not take a “comprehensive study”, or a mathematical relationship, to establish what is, at minimum, intuitively obvious - that an increase in airport noise of the type and magnitude portrayed in the SEIR will not be beneficial to learning. Second, it is improper for lead agencies to “defer formulation of possible mitigation programs by simply requiring future studies to see if mitigation may be feasible.” *Fairview Neighbors v. County of Ventura*, 70 Cal.App.4th 238, 244 (1999). Indeed, it is only where “after a thorough investigation, a lead agency finds that a particular impact is too speculative for evaluation, [that] the agency should note its conclusion and terminate discussion of the impact.” *Los Angeles Unified School District v. City of Los Angeles*, 58 Cal.App.4th 1019, 1026 (1997).

In *Los Angeles Unified School District*, a case only five years old, and involving the City of Los Angeles, proprietor of LAX, the court found that noise impacts on several schools from the proposed Warner Center Development in the San Fernando Valley were not too speculative for determination as claimed in the EIR, where “the authors of the EIR took precise measurements of existing traffic noise around Canoga Park High School and then used a Federal Highway Administration computer model to predict noise levels under alternative versions of the plan.” *Id.* On that ground, as well as a second ground, that sufficient reliable data had been developed to permit development of noise mitigation measures for residences in the area, *Id.* at 1028, the Court found that Los Angeles had failed to establish the reason why the same could not be done for the schools.

The same situation exists here. The SEIR contains what its authors, the lead agency, consider to be appropriate significance criteria based on several existing studies of classroom disruption, and analyzed in the INM, a Federal Aviation Administration model. Moreover, the SEIR contains what purports to be a definitive evaluation of noise impacts on residences, which

is accompanied by a number of mitigation measures, some of which are to be applied immediately upon Project implementation, and based on the determinations contained in the SEIR. There is, therefore, no cognizable reason, and the SEIR provides none, why reasonable, feasible mitigation measures to allay the impact of airport noise on children in 12 Inglewood schools should not be set forth in the SEIR.²

D. The SEIR's Analysis of Newly Awakened Population is Unclear and Potentially Inaccurate.

The SEIR reveals that the vast bulk of the population newly exposed by Alternative D to noise sufficient to awaken it on a regular basis, *i.e.*, 17,030 persons,³ lives in Inglewood, while all other affected jurisdictions, including the City of Los Angeles, Los Angeles County and El Segundo will experience a net decrease of up to 19,000 residents in population exposed to SEL levels sufficient to awaken. SEIR, Table 4.2-29. For that reason alone, Inglewood has a deep concern that the analysis of Alternative D's sleep impacts be accurate, understandable, and that proposed mitigation measures be adequate to mitigate those impacts. Thorough review of the SEIR and its Appendices fails to disclose relevant answers.

1. The Methodology Employed to Analyze Sleep Impacts of Aircraft Noise is Unclear and Leads to a Potentially Inaccurate Conclusions.

² To further complicate the issue, SEIR, Section 6.2.3, based eligibility for school noise mitigation on CNEL levels, a much higher, cumulative hurdle than the SEL criteria used to assess noise impacts on schools in SEIR Section 6.2. The SEIR should be revised to apply the relevant SEL criteria consistently to both the determination of noise impacts on schools and the eligibility for mitigation of those noise impacts.

³ When the population removed from the noise affected area by change in airfield configuration and resultant shift in the noise contour is considered, the net population in Inglewood exposed to regular awakening is 12,800 persons.

The SEIR uses a 94 dB SEL “noise contour” as a metric to measure aircraft noise sufficient to awaken. SEIR § 6.1.2 contains a description of the methodology used to calculate the location of the 94 dB SEL noise contour. That description is, however, unclear. The 94 dB level represented in SEIR Section 6.1.2 is based on a study that states that 10% of the population exposed to this level of noise will be awakened no more than once every 10 days. To establish a noise contour for operations that would occur once every 10 days, it appears that the methodology only considered aircraft operations that occur at least 0.1 times per day (or once every 10 days). If this is a correct understanding of the methodology, then the methodology is in error. If the methodology includes only aircraft that have at least 0.1 operations per day, then some operations have been excluded from the analysis. This could mean for example, that infrequent takeoffs to the east under Santa Ana conditions were not considered in the analysis. This omission would, of course, have a significant effect on Inglewood.

In effect, what is plotted in the SEIR is the 94 dB SEL contour (*i.e.*, the contour for 10% awakenings) for a subset of the total operations occurring at the airport. Therefore, the resulting analysis will be incorrect for two reasons: (1) It underpredicts the contour because it does not include all the flight operations at the airport; and (2) As the SEIR acknowledges that the model underpredicts SEL values by 0 to 3 dB, the resulting 94 dB SEL contour may also be underestimated by that amount. Finally, it is unclear from SEIR Section 6.1.2 whether the analysis of nighttime awakenings only included aircraft operations or also included ground runup operations which, in some instances, can be extremely noisy.

2. The Measures Proposed to Mitigate Awakenings are Incomplete and, Thus, At Least Partially Ineffective.

As a threshold matter, Inglewood appreciates the intent expressed in mitigation measure MM-LU-2, SEIR, Section 5, Project 5-20, to “incorporate residential dwelling units exposed to single event awakenings threshold into aircraft noise mitigation program.” However, SEIR Section 5 clouds that commitment by predicating the calculation of affected units on a comparison with “1992 65 CNEL contour”. Inglewood’s problem with that approach is twofold. First, the relevant baseline comparison throughout the SEIR for CEQA purposes is 1996. To suddenly employ 1992 contours as a baseline for comparison, without further explanation, renders the conclusion derived from that comparison suspect.

Inglewood is aware that the rationale for use of the 1992 contour is that, according to explanations offered in other forums, the 1992 contour represent the noisiest recent year due to the level of operations and the relative preponderance in the fleet of Stage 2 aircraft at that time. Nevertheless, neither the 1992 contour, nor data from 1992, are presented anywhere in the SEIR or relied upon in other sections. Therefore, further analysis of 1992 operations, noise levels, and

resulting contours, as compared to those for 1996 and 2000, the designated baselines for analysis in the SEIR, is required to justify use of 1992 contours in this isolated instance.

Moreover, the results of the comparison of Alternative D with 1992 contours is inconsistent with the results derived from comparison with the designated 1996 baseline. While the comparison with 1992 purports to result in 4,140 dwelling units and 13,170 residents of Inglewood newly exposed to nighttime awakenings, the comparison with 1996 results in 6,010 dwelling units and 17,930 residents newly exposed. Clearly, a measure that excludes 1,870 units and 4,760 residents will only incompletely mitigate Alternative D's noise impacts.

Second, while Inglewood appreciates the time and effort devoted to an application to the FAA for enforceable noise restrictions under 14 C.F.R. Part 161, that measure will also result in only incomplete mitigation. As SEIR, App. S-C1, Section 3.1.6 indicates, the Part 161 application will only eliminate gratuitous use of nighttime takeoffs to the east. For safety reasons, takeoffs to the east will still occur during Santa Ana conditions or when coastal fog limits visibility. As acknowledged in SEIR, App. S-C1, Section 3.1.6, these safety reasons account for the great majority of takeoffs to the east. Therefore, the mitigation measure that is the subject of a Part 161 application will be only intermittently applicable, and, thus, may provide little relief to the residents of Inglewood. Finally, SEIR, App. S-C1, Section 6.1.3 states that the Part 161 application will only apply to eastbound takeoffs between midnight and 6:30 a.m. However, SEIR, App. S-C1, Section 6.1 states that the analysis of nighttime awakenings applies to the hours between 10:00 p.m. and 7:00 a.m. Therefore, the proposed mitigation measure will not cover a period of two and one-half hours each night.

In the last analysis, the gravamen of the mitigation for nighttime awakenings is the sound insulation program identified in SEIR, App. S-C1, Section 6.1.3. However, without further clarification concerning the extent of the units and population that will be covered by the sound insulation program, the program appears inadequate to mitigate the full noise impacts of Alternative D.

E. The Expansion of the ANMP Contemplated in Mitigation Measure MM-LU-1 May Provide Only Limited Relief to Inglewood Residents Newly Exposed to Noise in Excess of 65 dB CNEL.

The SEIR makes painfully clear that the vast bulk of the population newly exposed by Alternative D to noise in excess of 65 dB CNEL will be in Inglewood. Specifically, Alternative D is projected to increase the number of Inglewood residents impacted by noise in excess of 65 dB CNEL by 4,190, when compared to the 1996 baseline (as opposed to zero in El Segundo, 790 in the City of Los Angeles, and 380 in Los Angeles County). Nevertheless, the scope of MM-LU-1's applicability to these newly affected populations is not clearly defined.

For example, while MM-LU-1 proposes to expand the existing ANMP to “mitigate land uses that would be rendered incompatible by noise impacts associated with implementation of the LAX Master Plan”, SEIR, 5-19, it also imposes criteria for inclusion in the ANMP that require the existing ANMP to be completed before expansion to newly impacted residences. As the current ANMP already involves thousands of units in Inglewood alone, not to speak of other communities; and as the process of sound insulation construction can be a lengthy and complex one, the almost 5,000 newly impacted residents of Inglewood may have to wait in line behind other residents of Inglewood and other communities for up to 10 years, all the while suffering the debilitating impacts on sleep, learning and living in general caused by Alternative D.

Moreover, as an alternative to insulation, MM-LU-1 proposes “acquisition of properties within the highest CNEL measurement zone” as well as those with “high concentrations of residents and other noise sensitive occupants . . .” SEIR, Project 5-19, 20. MM-LU-1, however, fails to identify the manner in which the housing needs of newly exposed residents will be accommodated after their properties are acquired. In fact, the SEIR, Section 4.4.3, rejects the necessity of acquisition, and consequently ignores the need for attendant relocation. [“Under Alternative D, there would be a substantial reduction in property acquisition compared to the other build alternatives. No residential acquisition is proposed . . .” SEIR, p. 4-333] Nor is there any discussion of the way in which, in the tight and expensive L.A. housing market, decent affordable housing will be provided, or made available through new construction.

In light of the size of the potentially affected population, most of which are in Inglewood, and its heavily low income and minority characteristics, MM-LU-1 is sorely inadequate to mitigate the impacts of any of the proposed alternatives.

F. The Data and Metrics Used in the SEIR’s Analysis of Alternative D’s Traffic Noise Impacts Are Inconsistent With Those Used in the Evaluation of its Aircraft Noise Impacts.

The methodology used in the SEIR’s analysis of Alternative D’s traffic noise impacts is unclear as to the data used in the evaluation of peak hour traffic noise, as well as inconsistent as between the metrics used to assess traffic and aircraft noise. These inconsistencies may render the SEIR’s conclusions regarding Alternative D’s cumulative noise impacts questionable.

The SEIR states that peak noise hour data, *i.e.*, data for the noisiest one hour period of the day, were used in the analysis of traffic noise. SEIR § 4.1.2.1.3. However, based on review of SEIR, App. SC-2, Roadway Noise Data, it appears that, in fact, either peak a.m. or p.m. traffic

data were used. These are not typically the noisiest hours of the day since traffic slows due to congestion. Thus, the SEIR's traffic noise analysis may not have captured the true extent of the Project's traffic noise impacts.⁴

⁴ It appears, although it is by no means certain, that the data in SEIR, App. SC-2 takes this into account by reducing traffic speeds for future years. However, a more accurate way of dealing with the problem would be to start with the correct data in the first instance.

Further, the metrics used to measure aircraft and traffic noise are inconsistent. The SEIR's aircraft noise analysis depends on the cumulative CNEL metric.⁵ The SEIR's significance criterion for traffic noise, however, is the 24 hour L_{eq} metric which is a predicate to, but not identical with, the CNEL significance criterion. Where the SEIR purports "for information purposes", to combine aircraft and traffic noise to estimate the total experienced noise, Section 4.1.2.1.3, p. 4-12, it does so by converting both traffic and aircraft noise to a 24 hour L_{eq} metric, rather than converting traffic noise to a CNEL metric. The result is a comparison of "apples and oranges", that deprives the public of the simplicity of a consistent metric. If using the L_{eq} metric would result in a more accurate characterization of the Project's noise impacts, its use would be acceptable. However, the SEIR does not claim that this is so.

In short, while the SEIR states that the computation of the combined noise impacts of traffic and aircraft are for "information purposes" only, the reality is that noise in the vicinity of the project will have multiple components, two of which are aircraft and traffic, and another, construction noise as set forth below. The SEIR has an affirmative responsibility to fully and accurately depict the cumulative impacts of all three.

G. The Impact of Construction Noise From the Proposed GTC on Residents of Inglewood Has Not Been Adequately Evaluated.

SEIR Section 4.1.6.4.3 states, in pertinent part, that: (1) as the closest noise sensitive uses to the GTC are more than 1,000 feet to the east across La Cienega Boulevard and the I-405 in the City of Inglewood; (2) because construction equipment noise of 86 dBA L_{eq} would dissipate to approximately 66 dBA L_{eq} at that distance; and (3) because the road traffic and other noise would mask any construction noise, the impact of construction noise on homes in Inglewood would be less than significant. In reaching that conclusion, the SEIR relies on a theory conclusively rejected by the court in *Los Angeles Unified School District, supra*, 58 Cal.App.4th at 1025.

In its EIR in that case, as in the SEIR here, Los Angeles reasoned that "the noise level around the schools is already beyond the maximum level permitted under Department of Health Guidelines so even though traffic noise from the new development will make things worse, the impact is insignificant." *Id.* After characterizing Los Angeles' position, the court rejected it, relying on *Kings County Farm Bureau v. City of Hanford*, 221 Cal.App.3d 692, 720 (1990).

"This ratio theory, the court explained, 'trivialized the project's impact' by focusing on individual inputs, not their collective significance. . . [T]he relevant issue to be addressed in the EIR on the plan is not the relative amount of traffic noise resulting from

⁵ The exceptions to the use of the CNEL metric is to assess noise impacts on schools and awakenings.

the project when compared to existing traffic noise, but whether any additional amount of traffic noise should be considered significant in light of the serious nature of the traffic noise problem already existing around the schools.” *Id.* quoting *Kings County Farm Bureau, supra*.

The SEIR’s analysis of the construction noise impacts of Alternative D is predicated upon precisely the same impermissible “ratio theory” as that rejected in *Los Angeles Unified School District*. The SEIR opines both that construction equipment noise would dissipate to a less than discernable level at a distance of 1,000 feet from Inglewood and that road traffic noise would mask any construction noise. While some analysis exists in the SEIR to support the former, none whatsoever exists with respect to the latter. In other words, it is yet to be determined whether traffic noise, when calculated using peak noise hour data, as well as peak traffic data, will sufficiently exceed the level of construction noise, the peak hours of which may be entirely different, to mask or obliterate its impacts on residents less than a fifth of a mile away. As the court held in *Los Angeles Unified School District*, “we do not know the answer to this question but, more important, neither does the City”. *Id.* at 1026. Without those answers respecting the Project’s cumulative traffic, aircraft and construction noise impacts, the SEIR is potentially inadequate.

IV. THE SEIR DOES NOT FULLY DISCLOSE THE PROJECT’S AIR QUALITY IMPACTS.

The SEIR’s air quality analysis is of questionable accuracy where: (1) the methodology employed in the analysis understates baseline emission concentrations, thus leaving substantial headroom within which to make the finding that the Project increases emissions without violating ambient air quality standards (“AAQS”); (2) understates emissions from aircraft; (3) overstates emissions benefits from electrification of aircraft ground support equipment and the use of gate-based power, and understates emissions impacts from construction equipment; (4) omits heavy duty construction and transport truck emissions from the analysis; and (5) improperly defers the conformity analysis required for all Federally funded projects pursuant to the conformity provisions of the Clean Air Act, 42 U.S.C. § 7506, *et seq.*

A. The Methodology Used in the Calculation of Background Pollutant Concentrations Leads to Understatement of Impacts.

To varying degrees, the determination of the Project’s environmental impacts is dependent upon the background environment with which the Project impacts are compared. With respect to a determination of air quality impacts, the accurate calculation of background concentrations is particularly crucial, because it is upon that base that the compliance of Project specific emissions with regional air quality standards is determined. If that base is

underestimated, the overall effect of airport improvements on AAQS compliance will be similarly understated. Here, it appears that the baseline concentrations upon which Alternative D's compliance is predicated are calculated through a methodology that artificially lowers background emissions levels so as to allow room for Project emissions to fall below maximum applicable AAQS.

The SEIR employs a methodology whereby future year background concentrations, excluding PM_{10s}, are determined by adjusting base year concentrations by the ratio of future south coast regional emissions to current south coast regional emissions. For PM₁₀, the process is similar but is based on the ratio of estimated future year PM₁₀ concentrations to current PM₁₀ concentrations in central Los Angeles. Both methods seem likely to produce optimistic (too low) background concentrations for LAX.

First, both methods assume that regional reductions affect all areas of the region equally. However, background concentrations, as well as future emission reduction influences are constrained by geography around LAX. Since the prevailing wind is from southwest to northeast, the Pacific Ocean represents a physical constraint and it is unlikely that background pollutant concentrations coming into LAX will be reduced in proportion to emission reduction occurring downwind. In addition, the emissions based approach assumes that fully 100% of the background can be reduced, *i.e.*, if emissions go to zero, ambient concentrations go to zero. While this may be true in an idealized situation, transport and biogenic emissions represent a floor below which air quality cannot be locally reduced. For example, emissions associated with shipping may represent a floor for background NO_x and SO₂ at LAX. The SEIR does not provide enough data from which to make that determination.

The SEIR does, however, provide additional evidence to support the conclusion that the Project's baseline concentrations are artificially reduced. For example, the SEIR's methodology assumes that emissions from LAX are already included in background concentrations, and, thus, they must represent conservative background pollutant concentration baselines for air quality analysis, as LAX emissions will be added on top of a background that already includes those same LAX emissions. This assumption is based on data concerning baseline short-term (sub-annual) background concentrations measured at an on-site monitoring station located just east of the southern runway configuration, and annual concentrations based on data collected at a SCAQMD monitoring facility in Hawthorne, located near, but southeast of LAX. Because, as set forth above, the prevailing wind direction for LAX area is southwest to northeast, the bulk of airport activity, including all terminal and motor vehicle operations, occur under the influence of a prevailing wind plume that is further north than the onsite monitoring station. While certain aircraft takeoff and queuing emissions are undoubtedly accounted for in the on-site baseline concentrations, these represent only a small fraction of overall airport emissions.

National Weather Service data for 1984 through 1992 at LAX demonstrates the likelihood that these monitoring data are not significantly impacted by LAX emissions. Winds are out of the west or southwest $48 \pm 6\%$ (or approximately $\frac{1}{2}$) of all hours in that period. To get a better idea of the significance of this distribution, if a circle were centered at LAX and split into 16 equal "slices", the wind would be blowing off the ocean through only two of those 16 slices for fully $\frac{1}{2}$ of all hours. Moreover, these winds would be blowing in a direction such that LAX emissions would have no influence on the off-site monitoring station and little, if any, influence on the on-site measurement. Perhaps most tellingly, winds moved in a prevailing south to north direction (from the bottom half of the circle to the top half) $82 \pm 3\%$ of all hours between 1984 and 1992. Thus, only during $9 \pm 2\%$ of all hours did wind move from the northwest quadrant of the circle toward the southeastern quadrant (*i.e.*, in the direction necessary to influence either the on-site or off-site monitors). Therefore, whatever influence LAX has on either site is clearly modest since the off-site station is located south of LAX and the on-site station is on the southeastern corner of the airport. Consequently, there is little influence from LAX on the off-site concentrations used as background, and only a slight influence on the on-site based background concentrations.

In summary, as a result of employing the specified methodology, 2015 background concentrations are potentially reduced by 50% for NO₂, 60% for CO, and 30-80% for PM₁₀. Clearly, these reductions provide substantial "headroom" for local emissions increases within the confines of the AAQS. Furthermore, these reductions appear to represent the most significant influence on forecasted pollutant concentrations in the years 2005 and 2015.

The overall sensitivity of the air quality analyses to the background concentration reduction is perhaps best recognized in examining the forecasted 2015 pollutant concentrations. Despite the 50% background concentration reductions for NO₂, annual average on-site NO₂ concentrations are forecasted to increase between 1996 and 2015. While the forecasted increase is not sufficient to cause a violation of the NO₂ AAQS, that may be entirely the result of the reduced background concentrations resulting from the flawed methodology employed. Clearly, the integrity of the AAQS compliance status hinges on the proper demonstration of background concentration propriety. Since this is the case, it is critical that assumed background concentrations be supported with appropriate analyses, and those analyses are currently lacking in both the DEIR and SEIR.

B. The SEIR Understates Aircraft Emissions.

Aircraft emissions are understated in the SEIR through utilization in the analysis of: (1) incorrect aircraft PM₁₀ factors; (2) incorrect taxi times; (3) incorrect default aircraft engine assignments; and (4) omission to consider reverse thrust emissions.

1. The SEIR Air Quality Analysis Utilizes Incorrect Aircraft PM₁₀ Emission Factors.

As set forth in Attachment 1 to this letter, the DEIR's air quality analysis was based on incorrect PM₁₀ emissions factors. As nothing has changed in the SEIR, this issue is again worthy of note. PM₁₀ emission factor estimation in the DEIR shows that the basic estimation approach yields an emission factor that only considers the basis nonvolatile portion of the particulate. An adjustment factor (that varies with fuel sulfur content) should be used to correct the estimate to total PM. As set forth in Attachment 1, this factor is estimated to be approximately 2.6 for low sulfur (about 70 PPMW) jet fuel and 14.7 for high sulfur (about 675 PPMW) jet fuel. As EPA data demonstrates that U.S. jet fuel averages about 600 PPMW sulfur, the appropriate adjustment factor for the SEIR would be about 13.2. However, as the SEIR uses unadjusted emissions factors, PM₁₀ emissions are underestimated by a factor of 13.

This alternative approach to PM emission factor estimation is based on a strong statistical relationship between measured PM and the inverse of measure NO_x (with co-efficients significant at 99+% confidence levels). With such a relationship, the entire existing database of aircraft NO_x emissions rates can be evaluated to develop aircraft engine and operating mode specific PM emissions rates. This approach produces PM emissions rates that range from 4 to 37 times higher (depending on operating mode) than those used in the DEIR and SEIR. The smallest differentials are observed at the highest thrust modes. For a typical landing/takeoff ("LTO") cycle at LAX (*i.e.*, using local times in mode), the SEIR appears to underpredict the aggregate PM emission factor by a factor of about 17. The effect on related PM air quality analysis is obvious.⁶

Interestingly, if the appropriate carbon-to-total PM emission factor correction of 13.2 is applied to the emissions rates used in the DEIR and SEIR, the differential between the two emissions factor estimation approaches is dramatically reduced, from a factor of 17 to a factor of 13. However, even this differential is worthy of investigation since mode specific differences are

⁶ Inglewood acknowledges that the available PM emissions testing database is both small and dated. It does not, however, agree with the DEIR that the age of available testing data renders it valueless. While engine technology has advanced relative to the engines represented in the database, the fundamental combustion characteristics that give rise to PM formation have not. Further, the claim that the existing aircraft emissions factors are not of value since they reflect total PM as opposed to PM₁₀ is also without merit. Virtually 100% of combustion related PM is PM₁₀, so any error resulting from the substitution of total PM for PM₁₀ is insignificant relative to the analysis errors contained in the DEIR and SEIR. Ironically, the PM emission factor estimation approach employed in both the DEIR and SEIR requires the very same assumption of equivalency between total PM and PM₁₀.

in and of themselves significant and the overall air quality impact depends on how individual mode significance changes over time.

2. The SEIR Inaccurately Represents Aircraft Taxi Times.

The DEIR did not present any aircraft to taxi/queue times. The SEIR, however, does present a single set of taxi/queue times that are stated to have been “used to estimate aircraft emissions for all alternatives in both horizon years”. SEIR, App. S-E, p. 10. However, based on analysis of the data set forth in SEIR App. S-E, this statement does not appear to be accurate. As shown in Table 1 below, the main benefit ascribed to Alternative D is a reduction in taxi times.

TABLE 1

	NO _x (tpy)	VOC(tpy)	CO(tpy)	SO ₂ (tpy)	PM-10(tpy)
Taxi Emissions - NA/NP Alternative	723.3	794.9	4,381.6	89.9	17.8
Taxi Emissions - Alternative D	659.2	707.6	3,956.6	80.9	14.6
Taxi Emissions Difference	-64.1	-87.3	-425	-9	-3.2
Aircraft Emissions - NA/NP Alternative	5,154.9	1,204.1	6,668.7	232.5	70.2
Aircraft Emissions - Alternative D	5,171.7	1,111.2	6,240.7	223.7	62.0
Aircraft Emissions Difference	16.8	-92.9	-428.0	-8.8	-8.2
Percent of Total Difference Due to Taxi	-382%	94%	99%	102%	39%

As also shown in Table 1, with the exception of PM₁₀, changes in taxi related emissions account for virtually 100% of the claimed reductions in aircraft emissions from Alternative D. Therefore, it would be methodologically unlikely that the same taxi times were used for all airport alternatives, because if that were so, the differences between the alternatives would be far less distinguishable.

As the bulk of aircraft VOC and CO emissions are generated during taxi; and although NO_x emissions rates are low during taxi, the amount of time spent in taxi mode results in a significant contribution to overall aircraft NO_x emissions, it is important that taxi time be accurately modeled. The SEIR contains insufficient information to allow an appropriate evaluation.

3. The SEIR Utilizes Incorrect Default Aircraft Engine Assignments.

The SEIR sets forth the assumed aircraft engines for all modeled airframes. It appears that these assumptions reflect the EDMS version 4.11 Default Engine Assignments without exception. While such an assumption would not affect the relative impacts of the various LAX

alternatives, it can have a significant impact on the absolute level of aircraft emissions and the magnitude of associated ambient concentrations. The EDMS default engine reflects the “most popular” engine for an airframe based on total airframe sales. For a particular airport, total airframe sales may or may not be an accurate indicator of local conditions due to variations in airline specific activity (e.g., local vs. national). Different airlines favor different airports and the associated traffic into and out of those airports is biased toward local airline distributions. Thus, aircraft engine assignments should, at a minimum, be conducted on the basis of the local airline mix, which is unlikely to be consistent with EDMS default assumptions. The SEIR does not contain an analysis based on local airline mix and, thus, its conclusions with regard to aircraft emissions are not definitive.

4. The SEIR Air Quality Analysis Does Not Include Reverse Thrust Emissions.

The SEIR, like the DEIR, omits from its air quality analysis emissions from aircraft reverse thrust operations, on the ground of lack of adequate emissions factors and short usage times. Both of these claims are, however, misleading. Reverse thrust is essentially a high thrust operating mode and emissions factors for such modes (*i.e.*, climb out and takeoff) are readily available. Common practice utilizes takeoff emission factors. It is true that the time in mode for reverse thrust operations is short. However, high thrust modes produce very high NO_x per unit time relative to other operating modes such as aircraft taxi. For example, at a commonly utilized reverse thrust mode time of 15 seconds, overall effective takeoff time would increase by approximately 25% (approximately one minute standard takeoff time plus 0.25 reverse thrust minutes vs. one minute without reverse thrust). This, in turn, increases NO_x by 25% relative to takeoff alone. Since takeoff accounts for about 35% of total aircraft NO_x under all alternatives, including the No Project alternative, the overall aircraft NO_x inventory could increase by about 10% simply due to the inclusion of reverse thrust related emissions. Without some enforceable measure prohibiting reverse thrust operations, there is no supportable rationale for excluding reverse thrust emissions from the air quality analysis.

C. The SEIR Overstates Emissions Benefits from Electrification of Aircraft Ground Support Equipment and the Use of Gate Based Power.

As a threshold matter, emissions factors employed in the DEIR for off road engines, including, but not limited to, construction equipment and aircraft GSE were significantly underestimated by the use of outdated emissions factor sources. The SEIR purports to have corrected that flaw though the use of emissions factors for off road construction equipment derived from the California Air Resources Board (“CARB”) OFFROAD Emission Factor Model. This would be the correct approach. However, it is not possible to confirm that the revised emissions factors are derived from the OFFROAD model, as the SEIR contains only an aggregate emissions summary (as opposed to the DEIR’s actual emissions factors for comparison).

With respect to GSE, the SEIR relies on emissions factors derived from the latest version of the FAA's EDMS model (updated since the DEIR). While the emissions factors in the SEIR also appear consistent with those contained in EPA's NONROAD Emission Factor Model, the SEIR still raises significant concerns regarding the overall propriety of the GSE emissions analysis.

1. The SEIR Does Not Validate the Assumptions Contained in FAA's EDMS Model with Real Data.

Like the DEIR, the SEIR continues to rely on the FAA's EDMS model to estimate the LAX GSE population and equipment characteristics (*e.g.*, horsepower, hours of use, load factor). Given that the current GSE population and most of the associated operating parameters for LAX are already known, it is appropriate to validate the EDMS model assumptions with actual LAX conditions. Ideally, the current assumptions should be replaced in their entirety with known LAX data. At a minimum, consistency should be demonstrated. The FAA has facilitated the use of actual airport data through their latest release of the EDMS model (Version 4.11, identical to that used to support the SEIR) by allowing users to replace aircraft based GSE activity assumptions with airport specific "census" data. The analysis in the SEIR should take advantage of this opportunity to establish the air quality analysis' accuracy.

2. The SEIR's Assumption That Alternative D Will Involve GSE Electrification and the No Project Alternative Will Not is Groundless.

Like the DEIR, the SEIR posits a wide spread GSE electrification program under all four build alternatives, while retaining a large percentage of fossil fuel powered GSE under the No Project alternative. While this GSE electrification program is asserted to be the most effective mitigation measure set forth in the SEIR, there are no grounds to assume that GSE will not be similarly electrified under the No Project alternative, thus, eliminating any differential resulting from the use of fossil fuel powered GSE between the No Project and build alternatives.

First, its is arbitrary to apply GSE electrification only to the build alternatives, as there are no specific constraints to implementation under the No Project alternative. Moreover, electrification of GSE is cost effective from a market standpoint today so whatever incentive or mandate will be offered under the build alternatives to move toward electrification could just as easily be applied today to generate emissions reductions under a No Project alternative.

Even ignoring the tenuous relationship between the build alternatives and GSE electrification as a mitigation measure, by far the most troubling issue is that GSE electrification appears to be accounted for in the "unmitigated" emission estimates for all build alternatives. If this is a correct assessment, no additional emissions reductions will be achieved through GSE

electrification. For example, unmitigated GSE emissions for Alternative D and the No Project alternative (from SEIR App. S-4, Attachment N), are virtually identical in terms of aircraft and, thus, GSE activity. Although there is no reason set forth in the SEIR to expect GSE to emit any differently between an unmitigated implementation of Alternative D and the No Project alternative, the data in Attachment N demonstrates that Alternative D presents a substantial reduction in emissions of all pollutants over the emissions in the No Project alternative.

TABLE 2

	NO _x (tpy)	VOC(tpy)	CO(tpy)	SO ₂ (tpy)	PM-10(tpy)
NA/NP Alternative	618.7	240.4	5,685.9	11.4	24.0
Alternative D	135.5	88.1	1,523.2	1.4	30.8
Percent Change	-78%	-63%	-73%	-88%	28%

There are only two possible explanations for the reported differences. Either the Table in Attachment N is incorrectly labeled, and actually reflects mitigated emissions differentials, or the GSE electrification is included in the “unmitigated” emissions from the Project.

In the final analysis, it is clear that the reason air quality impacts under Alternative D are reported to be less than those of the No Project alternative can be traced almost entirely to emissions reductions associated with GSE and aircraft taxi times. In fact, impacts for all other emissions sources under Alternative D are either null or negative compared to the No Project alternative.

TABLE 3

	NO _x (tpy)	VOC(tpy)	CO(tpy)	SO ₂ (tpy)	PM-10(tpy)
NA/NP Alternative	6,278.8	1,775.0	14,413.1	251.8	170.0
Alternative D	5,746.5	1,625.0	9,660.3	246.4	187.1
Total Emissions Difference	-532.3	-150.0	-4,752.8	-5.4	17.1
GSE Emissions Difference	-483.2	-152.3	-4,162.7	-10.0	6.8
Percent of Total Difference Due to GSE	91%	102%	88%	185%	40%
Aircraft Taxi Difference	-64.1	-87.3	-425.0	-9.0	-3.2
Percent of Total Difference Due to Taxi	12%	58%	9%	167%	-19%
Percent of Total Difference Due to GSE and Taxi	103%	160%	97%	352%	21%

If that conclusion is correct, then all air quality benefits accruing from GSE electrification in Alternative D could just as readily be applied to the No Project alternative, rendering any air quality benefits from Alternative D ephemeral at best.

4. The SEIR Overstates the Emissions Benefits of Gate Based Power and Understates the Potential for Auxiliary Power Unit Emissions.

Like the DEIR, the SEIR assumes that 100% of air carrier gate power and conditioned air needs will be satisfied by gate-based electrically powered systems, as opposed to fossil fuel powered Auxiliary Power Units ("APU") or GSE. This assumption is overly optimistic because, even under conditions where gate based equipment is available, not all airlines or aircraft will utilize it consistently. Although the assumption of 100% availability and usage affects the No Project alternative and build alternatives equally, it is necessary to account for the full range of expected emissions in order to determine AAQS compliance. Without some enforceable policy requiring that gate base systems (both air and power) be used, and that any onboard APU be shut down until needed for main engine startup, a more realistic assumption for aircraft emissions purposes would be to base the fraction of aircraft that rely on gate base systems on the system usage rate for currently equipped gates at LAX.

Moreover, perhaps as a result of the assumption of universal use of gate based power, the SEIR assumes an emission factor of zero for all APU. While the impact of this assumption is buffered by the assumption of limited APU usage, APUs are still assumed to operate for seven minutes, at the time of main engine startup and shut down, and emissions during this period should be fully considered. Further, if the APU usage rate is corrected to better reflect actual gate based system usage, APU emissions could increase to 40 minutes or longer for a wide bodied aircraft, a level which would more properly reflect maximum short term emissions rates and maximum short term ambient concentration impacts. Without inclusion of APU emissions, it appears that the SEIR's air quality analysis is flawed.

5. The SEIR Relies on Outdated Load Factors for Off Road Equipment.

While the SEIR utilizes revised emissions factors derived from ARB's OFFROAD Model to assess the emissions impacts of off road construction and other equipment, it does not similarly employ revised operational load factors. Instead it relies on load factors derived from the CEQA Air Quality Handbook published in 1993. As considerable information has been collected in the last decade, relying on load factors from 1993 is likely to skew the air quality analysis in ways it is not possible to anticipate without the provision of relevant data.

6. The SEIR's Air Quality Analysis Omits Heavy Duty Trucks From Its Fleet Mix.

Perhaps the most surprising omission from the SEIR's air quality analysis is from the assumed fleet mix for vehicles on all airport roadway links, set forth in SEIR, App. S-4, Attachment J, which lacks any accounting for heavy duty truck travel. As Alternative D includes 3.1 million square feet of cargo space on airport property, not to speak of the cargo space that may be utilized off airport by cargo carriers; as Federal Express and other cargo carriers operate substantial fleets of heavy duty diesel trucks; and as heavy duty diesel trucks are large emitters of NO_x and other pollutants, omission of heavy duty trucks from the on road fleet mix will have a substantial impact on the estimation of NO_x emissions from Alternative D and other build alternatives which may render the SEIR's air quality analysis inadequate.

D. The SEIR, Like the DEIR, Improperly Defers the Requisite Conformity Analysis.

The SEIR acknowledges the applicability of Federal conformity requirements, as set forth in Clean Air Act, 42 U.S.C. § 7506, and its implementing regulations, but, like the DEIR, defers both the conformity analysis and potential conformity determination to a final EIR/EIS. Such an approach makes it impossible for the public to comment constructively on either potential emission mitigation measures or the conformity process, since these processes and their result will be released for comment only after the underlying decision making has been finalized.⁷

Moreover, the absence of a draft conformity analysis in the SEIR has more fundamental impacts. The Clean Air Act specifies, in pertinent part, that "no department, agency, or instrumentality of the federal government shall engage in, support in any way or provide financial assistance for, license or permit, or approve, any activity which does not conform to an implementation plan after it has been approved . . ." Clean Air Act § 7506(c)(1). Without at least a preliminary conformity analysis, it is impossible to document Alternative D's potential compliance or noncompliance with state air quality implementation plan (or verification that the project is already included in the State Implementation Plan). Absence of at least a draft conformity analysis at this stage of the Project's documentation violates the most fundamental goal of CEQA, *i.e.*, "to encourage informed public information and decision making," and, consequently, may constitute a fatal flaw in the SEIR.

V. THE SEIR'S ANALYSIS OF SURFACE TRAFFIC IMPACTS IS INCOMPLETE.

The SEIR's analysis of Alternative D's surface traffic impacts, like the more global analysis of Alternatives A through C in the DEIR: (1) omits analysis of certain critical intersections, and reaches conclusions based on data absent from the SEIR, or inconsistent with data contained in other planning documents for the same areas; (2) omits analysis of the traffic impacts, either beneficial or detrimental, of proposed off airport FlyAway terminals; (3) provides

⁷ Inglewood hereby reserves its right to comment on the Draft and Final Conformity Analyses and/or determination for the Project.

incomplete explanation of the Project's trip generation potential, including trip distribution and its potential impact on Inglewood; (4) fails to explain the way in which the proposed mitigation for the traffic impacts of construction, and the ultimate buildout of the Northside project, will be effectively implemented; and (5) fails to address the direct as well as cumulative traffic and parking impacts on Inglewood of the construction and subsequent utilization of the GTC.

A. The SEIR's Analysis of Baseline, as Well as Current, Intersection Traffic Levels Lacks Analytic Support.

The SEIR's analysis of 1996 and 2001 updated baseline intersection traffic levels, for comparison with Alternative D's influence on traffic impacts at selected intersections, omits or obscures critical information which makes verification of the SEIR's conclusions difficult, if not impossible.

1. The SEIR's Conclusions Regarding the Continuing Relevance of the 1996 Baseline for Traffic Purposes is Unsupported.

SEIR, Section 4.3.2.3 contains an analysis of 38 intersections, updating traffic conditions reflected in the 1996 environmental baseline, apparently for the purpose of determining the continuing applicability of the 1996 base year. The updated data purportedly show a "combined" average annual growth rate for all intersections analyzed of "approximately 1.5%" and "1% for the a.m. and p.m. peak hours respectively." SEIR, Section 4, p. 4-244. On that basis, the SEIR concludes that: (1) the traffic growth rate is consistent with general population growth rate in the area; (2) that it is a "small" growth rate; and (3) 1996 is still the applicable environmental base condition.

The above conclusions are problematic. First, no background data are provided to support them. Second, the analysis purports to be of "combined intersections", but no methodology is set forth to explain the means by which the intersections were "combined" for statistical purposes, or, more fundamentally, the meaning of the term "combined" (*e.g.*, statistically, arithmetically, other). Since the essence of traffic analysis is the determination of differential traffic impacts at different intersections, and as no such analysis is set forth in the SEIR, the integrity of this "combined" approach remains unestablished.

Third, as a result, there is no data with which to verify the SEIR's conclusion regarding consistency with the growth rates of the surrounding area, nor can the SEIR's conclusion that this is a small growth rate be substantiated. In fact, assuming the 1% growth rate in a.m. and p.m. peak hours is accurate; and assuming (for ease of computation only) the "combined" traffic at all 38 intersections totals 10,000 cars in each peak hour, the increase in the number of cars over the designated five year period is 510, or over 5%. Thus, even if 5% is deemed "small", if the total number of peak hour vehicles substantially exceeds 10,000, which it is more than likely to do, the

actual traffic growth will not be small, casting doubt on the utility of the 1996 baseline for traffic comparison purposes.

2. The SEIR's Analysis of Traffic Impacts at Individual Off-Airport Intersections Conflicts with That of Other Contemporaneously Prepared Environmental Documents for Other Projects in the Same Area.

The SEIR was not prepared in a vacuum. It acknowledges that other projects are being planned and will be carried out contemporaneously with Alternative D. The environmental documentation for one of those cumulative projects, the Village at Playa Vista, was published as late as August, 2003. A comparative analysis of the Playa Vista EIR with the SEIR reveals significant discrepancies between the analyses of what are substantially the same relevant areas.

For example, the Playa Vista EIR identified two intersections not mentioned in the SEIR: (1) Centinella at La Brea; and (2) La Brea at Manchester, both apparently within the analysis area for the SEIR. Both intersections were identified as level of service F for both a.m. and p.m. hours, even without the Project. Since both the LAX and Playa Vista projects are geographically proximate, the baseline traffic analysis should use substantially the same assumptions and data, with the same results.

However, even intersections that are analyzed in both the SEIR and the Playa Vista EIR had notably different volume to capacity ratios and levels of service. The SEIR contains a table of the projected traffic in 2008 for Alternative D. The Playa Vista EIR provides similar information for the horizon year 2010. The following Table compares the levels of service for those two projections.

TABLE 1 COMPARISON LEVEL OF SERVICE PROJECTIONS

Intersection	A.M. Peak		P.M. Peak	
	LAX	Playa Vista	LAX	Playa Vista
Aviation - Arbor Vitae	D	B	B	D
La Cienega - Arbor Vitae	E	B	E	C
Aviation - Manchester	F	F	D	E
La Cienega - Manchester	C	E	D	E
Interstate 405 NB - Century	B	F	A	B

The discrepancies in projected levels of service, *i.e.*, the lower levels of service reflected in the Playa Vista EIR, are not explained by any data or analysis contained in the SEIR.

B. The SEIR Contains No Analysis of the Traffic Impacts of the “FlyAway” Terminals.

The SEIR indicates that a series of new “FlyAway” locations are incorporated into Alternative D. Section 4.3.2.9.2 states that “the development of several new FlyAway away remote terminals is proposed to reduce the amount of vehicle traffic associated with travel to and from LAX,” and that development of the “FlyAway” remote terminals would depend largely on the existing use and land use setting of the proposed site. The SEIR does not, however, designate the location of those proposed “FlyAway” remote terminals, nor does it analyze their impacts on traffic, either at LAX, or at their remote sites. Further, the SEIR does not indicate the amount of traffic which would be diverted from LAX by the use of these remote facilities.

Finally, the SEIR does not acknowledge that the use of remote sites does not eliminate the effects of traffic, but simply moves them to another location. As one of the suggested locations for a “FlyAway” terminal is in Inglewood, Inglewood has a cognizable interest in the anticipated traffic impacts of the use of remote sites, and as they are an integral strategy of Alternative D, the designated information is not “too speculative” to provide for public review at this point.

C. The SEIR Fails to Adequately Analyze the Trip Generation Potential of Alternative D, its Construction, or its Projected Ancillary Development At, among Others, LAX Northside.

The SEIR fails to address at least three issues fundamental to the analysis and projection of Alternative D’s trip generation potential.

First, the SEIR does not explain why, with roughly the same passenger and cargo activity, the No Project alternative and Alternative D generate different trip levels. The EIR states that facilities that comprise Alternative D were designed to serve an activity level similar to the scenario adopted by Southern California Association of Governments for the 2001 Regional Transportation Plan. This is an activity level of 78.9 million annual passengers. The No Project alternative assumes 78.7 million annual passengers. Nevertheless, even with the roughly equivalent numbers of passengers, a.m. and p.m. peak hour traffic volumes with Alternative D are projected to decrease, while they are projected to increase under the No Project alternative.

Second, the SEIR fails to explain the way in which a fundamental traffic mitigation measure, the trip cap on the Northside project, can be effectively implemented. The entire off-airport surface traffic assessment turns on the conclusion that there will be less traffic in the future as a result of the Project than there will be if the Project is not approved. The basis for this prediction is the reduction in traffic for “collateral trips”. For example, for

Alternative D, p.m. peak hour passenger and related trips are anticipated to increase by 1,198. However, there is a projected reduction of 7,825 collateral trips, resulting in a net decrease in trips of 6,627.

The source of the collateral trip reduction is, apparently, the change in the land use for the projected Northside and Continental City projects. SEIR, Appendix S-2b provides the basis for the projected reduction in collateral trips.

	A.M. Peak			P.M. Peak		
	No Project	Alt. C	Alt. D	No Project	Alt. C	Alt. D
Northside	7,217	3,922	3,922	7,131	4,423	4,421
Continental City	5,323	0	0	5,348	0	0
Manchester Square	0	212	212	0	233	233
TOTAL	12,540	4,134	4,134	12,479	4,656	4,654

The issue associated with the “collateral trip” reduction is the discretionary actions needed to modify the allowable land uses on the Northside and Continental City properties.

SEIR Section 4.2, Land Use, sets forth a “master plan commitment” that states:

“to the maximum extent feasible, all [Q] conditions from City of Los Angeles Ordinance No. 159.526 that address the LAX Northside project area will be incorporated by LAWA into the Zoning Code Amendment and LAX Master Plan implementing Ordinance for the Westchester south side project. Accepting that certain conditions may be updated, revised, or determined infeasible as a result of changes to the LAX Northside project, the final [Q] conditions for the Westchester south side project will insure that the level of environmental protection afforded by the full set of LAX Northside project [Q] conditions is maintained.”

“CEQA requires agencies to implement feasible mitigation measures or alternatives identified in the EIR.” *Fairview Neighbors, supra*, 70 Cal.App.4th at 243. Further, as set forth above, “it is improper for lead agencies to defer formulation of possible mitigation measures by simply requiring future studies to see if mitigation may be feasible.” *Id.* at 244. Thus, the suggestion that the trip cap on the Northside project, the principal mitigation measure for Alternative D’s off airport surface traffic impacts, may, at some future time, for reasons as yet undisclosed, be deemed infeasible, is unacceptable under CEQA.

In fact, it is readily ascertainable even now that the trip cap may not, in fact, be feasible. First, both the Northside and Continental City projects have approved entitlements, allowing 4.5 million square feet of development in the Northside project alone. Alternative D has no impact on this entitlement. Thus, the SEIR's projection that the Northside project, while remaining at the same density but, in some undisclosed manner, generating fewer trips than it would have before Alternative D, is unsupported.

Finally, the SEIR appears to double count the traffic benefits of the trip cap. On the one hand, the SEIR relies on the mechanism of "land acquisition" for a reduction in traffic of 2,150 vehicles per hour in the a.m. peak hour, and 1,973 vehicles per hour in the p.m. peak hour. On the other hand, the SEIR contemplates that "space would be available in the LAX Northside development to accommodate compatible businesses displaced by Alternative D [land acquisition]", SEIR, p. 3-49. The SEIR, thus, subtracts traffic from peak hour totals due to land acquisition; relocates the "compatible" businesses to the Northside project; and, ultimately, imposes a trip cap that allegedly accounts for additional traffic reduction, even though the reduction in traffic attributable to the acquisition of certain businesses is apparently mooted by their relocation to the Northside development. By that means, the SEIR takes advantage of two potential mitigation measures: (1) the traffic reduction due to elimination of certain businesses; and (2) the traffic reduction due to the Northside project trip cap, neither of which, the SEIR acknowledges, may ultimately be realized.

D. The SEIR Fails to Adequately Document the Mitigation of Off-Airport Construction Traffic Impacts.

The SEIR is emphatic that "... the project would be managed to ensure that there would not be any notable construction-related traffic generated by the project during those critical [a.m. and p.m. peak] hours." SEIR, p. 4-264. [Emphasis added.] In fact, the SEIR claims that construction traffic would be actually eliminated during the a.m. and p.m. peak hours, and virtually eliminated during the airport peak hour.

The SEIR, however, contains no discussion of the way in which "management" ensures this beneficial hourly redistribution of construction traffic. For example, there is no explanation of the way in which 2,449 employee trips will arrive by 7:00 a.m. but there will be no truck arrivals or departures until 11:00 a.m. Similarly, there is no explanation of the way in which "management" will ensure that there are no truck trips between 4:00 p.m. and 7:00 p.m., while allowing 120 trips per hour between 7:00 p.m. and midnight. Further, there is no indication of the way in which "management" will ensure that construction related truck trips will not divert onto residential surface streets in the vicinity of the project, absent constant monitoring by police or other kinds of security.

In short, the mitigation measures for construction related traffic are conceptual at best. Absent more information concerning the way in which they will be implemented and enforced, proposed mitigation measures, while generous in origin, must be considered largely infeasible.

E. The SEIR Does Not Address the Way in Which Traffic Impacts from Utilization of the GTC Independently, or Cumulatively With Construction Traffic, Will be Mitigated.

The SEIR acknowledges that the GTC is located as close as 1,000 feet across the I-405 freeway from residences in the City of Inglewood, and, further, that the GTC will be the “primary access point for all passenger drop-off and pick-up and vehicle parking”, SEIR, p. ES-19, under the assumptions of Alternative D. The SEIR further acknowledges that vehicles would access the GTC from, among others, eastbound Century Boulevard, and that direct access to Century Boulevard would be available for west bound traffic. SEIR Section 4.3.1.6.1.2, p. 4-226, 227. It is, therefore, reasonable to assume that the greatest preponderance of all LAX-bound traffic (847,394 vehicles in the year 2000, SEIR, Table S4.3.1-2) will terminate as close as 1,000 feet from the homes of Inglewood citizens. Moreover, the SEIR further acknowledges that demand for parking will exceed parking capacity under Alternative D, SEIR, Table S4.3.1-7, p. 4-235. Nevertheless, the SEIR gives short shrift to the potential surface street impacts of travelers looking for parking in lots that are already full, as well as those reluctant to pay the price of parking on City owned lots, or attempting to avoid delays in accessing crowded parking facilities.

As important, the SEIR fails to fully address the construction traffic impacts on proximate surface streets in Inglewood. While it acknowledges that “when the ITC comes on line, there is expected to be a substantial shift in airport traffic patterns”, SEIR, Section 4.3.2.6.2.2, p. 264, and that “the SEIR’s general approach and methodology does not account for construction traffic for the three primary peak hours”, SEIR, Section 4.3.2.6.2.2, p. 264 [emphasis added], the SEIR does not similarly acknowledge the same potential impact resulting from the opening of the GTC. Instead, it states only that “the facility is not expected to be opened until after 2008, at which time most of the final mitigation plan should be in place.” SEIR, Section 4.3.2.6.2.2., p. 264 [emphasis added].

The SEIR misses the point. The only mitigation offered is that “the project would be managed to ensure that there would not be any notable construction related traffic generated by the project during those critical hours.” SEIR, Section 4.3.2.6.2.2., p. 4-264, 265. Therefore, the SEIR does not offer sufficient firm mitigation to compensate for the potential adverse impacts arising from the normal but unanalyzed operation of the GTC, let alone the cumulative surface traffic impacts arising from Project construction, which is anticipated to last a minimum of seven years and perhaps as many as 12-13 years after the 2008 anticipated completion of the GTC.

In summary, the SEIR ignores Alternative D's surface traffic impacts on Inglewood, arising not only from traffic accessing the GTC, but from parking and construction traffic as well.

VI. THE SEIR'S ATTEMPT TO COMPLY WITH THE FEDERAL ENVIRONMENTAL JUSTICE PROGRAM IS PATENTLY INADEQUATE.

The Environmental Justice Section [Section 4.4.3] of the SEIR falls far short of the mark for compliance with the Federal Environmental Justice Program. Executive Order 12898 and the Department of Transportation's ("DOT") implementing order, DOT Order 5610.2, require that, in the planning and development of any program or activity receiving Federal financial assistance, project proponents must not only identify disproportionately high and adverse environmental and health risk effects of the project on minority and low-income populations, but also ensure that those effects are avoided, minimized or mitigated. [DOT Order 5610.2, 5.d; 6.b.(2)]

DOT Order 5610.2 further mandates that DOT programs and activities that will have a disproportionately high and adverse effect on populations protected by Title VI be carried out only if, among other things: (1) alternatives that would avoid or reduce the disproportionately high and adverse effects are not practicable, taking into account the social, economic and environmental effects of avoiding or mitigating the adverse effects [DOT Order 5610.2 §7.c]; and (2) alternatives that would have less adverse effects on protected populations (and still satisfy the need for the program) would either (i) have other adverse social, economic, environmental or human health impacts that are more severe, or (ii) involve increased cost of extraordinary magnitude. [Order 5610.2. §7.d.(2)]. "The findings, determinations and/or demonstration made in accordance with [DOT Order 5610.2, Section 7] must be appropriately documented, normally in the environmental impact statement . . ." DOT Order 5610.2 § 7.(f.)

The SEIR acknowledges that the LAX Master Plan Project will have overwhelmingly disproportionate Land Use and Relocation, Airport Noise, Air Quality and Health Risks impacts on minority and low-income communities located east of LAX, specifically including the City of Inglewood. [SEIR, Section 4.3.3]. However the SEIR: (1) fails to address project alternatives that would reduce or avoid those impacts; (2) incorrectly concludes that construction noise impacts will not fall disproportionately on minority and low-income communities east of LAX; (3) fails to propose a viable jobs benefit program to compensate for the Project's adverse environmental impacts including those of construction which will in fact fall disproportionately on minority and low-income communities; and (4) fails to explore mitigation measures which would have fewer disproportionate adverse environmental impacts on minority and/or low-income communities located east of the Airport. In addition, Section 4.4.3.4 states that no Master Plan Commitments for environmental justice are proposed. [SEIR, p. 4-138]

In Section 4.4.3.6, the SEIR states that LAX will work with the FAA and affected communities to develop mitigation programs and if, after those programs receive further input, the FAA concludes that disproportionately high and adverse human health and environmental effects on minority and low-income populations would still occur, “findings under the DOT Order would have to be made prior to project approval and the Final EIS/EIR would disclose those findings.” [p. 4-335] However, as set forth above, it is “improper for lead agencies to defer formulation of possible mitigation programs by simply requiring future studies to see if mitigation may be feasible.” *Fairview Neighbors, supra*, 70 Cal. App. 4th at 244. Moreover, the SEIR does not need additional studies as it already concludes unequivocally that, despite the proposed mitigation, the adverse environmental and human health impacts of the Project, under any alternative, will fall disproportionately on minority and low-income communities east of the Airport. [See, e.g., SEIR, pp. 4-321, 4-323, 4-424, 4,329]

Finally, the SEIR relies in part on a Memorandum of Understanding (“MOU”) between Los Angeles and Inglewood for compliance with the mitigation requirements of the Environmental Justice Program [p. 4-337]. The SEIR does not disclose, however, that the MOU, which addresses measures involving residential noise insulation, air conditioning and studies to improve compliance with over-the-ocean takeoff and night-time over-ocean procedures, is terminable at will, by either City, and will expire by its own terms in February, 2011, at least four, and more likely 10 years before final implementation of the Project. Therefore, MOU, like the remainder of the suggested mitigation measures, does not create a sufficient commitment to Inglewood to comply with the mandates of Executive Order 12898 and DOT Order 5610.2.

A. The SEIR Fails to Adequately Address Avoidance or Minimization of the Project’s Adverse Environmental and Health Risks Impacts Which Would Fall Disproportionally Low Income and Minority Communities Including Inglewood.

The SEIR acknowledges that the Project will have overwhelmingly disproportionate adverse impacts on Inglewood, a predominately minority and low-income community, in the areas of Land Use and Relocation, Airport Noise, Air Quality and Health Risks. The SEIR fails, however, to address avoidance or minimization of those impacts.

Environmental Justice Section 4.4.3.5.1 acknowledges that noise impacts associated with all alternatives will fall disproportionately on minority and low-income communities and that, under Alternative D, by Year 2015, approximately 93 percent of those newly exposed to high noise levels [4,030 residents] will be minority and/or low-income residents [SEIR, p. 4-324], and 85 percent of those newly exposed to single event noise awakening [15,340 residents] would be located within minority and/or low-income communities. [SEIR, p. 4-324].

The effects of aircraft noise on public schools will also fall on schools located predominately within minority and/or low-income communities. Eleven of the 12 public schools that will be newly exposed to the adverse impacts of increased aircraft noise levels or the 94 dB SEL noise contour by 2015 are located within the Inglewood Unified School District. [SEIR, p. 4-324]

Despite recognition of these severely disproportional noise impacts on minority and low-income communities, including Inglewood, and an acknowledgment that proposed mitigation will be inadequate where, after sound insulation, minority and low-income communities will still be faced with adverse effects of high outdoor noise levels [SEIR, p. 4-329], the SEIR does not address avoidance or minimization of those impacts, as required by the Federal Environmental Justice Program.

For example, Environmental Justice Section 4.4.3.5.5.1, Relocation of Residences or Businesses, states that, under Alternative D, "No residential acquisition is proposed, and the number of businesses that would need to [be] acquired and relocated would be reduced to 38." [emphasis added]. In that terse sentence, the SEIR eliminates from consideration a viable means for avoiding Project impacts on low-income and minority communities. As neither LAX nor its surrounding communities can be conveniently moved, the feasible option is to move those residents who are adversely impacted.

Moreover, the SEIR is internally inconsistent on this issue. Land Use Mitigation Measure MM-LU-1 calls for mitigation of land uses that would be rendered incompatible by the noise impacts of the Project by means of sound insulation or acquisition of residences, schools, hospitals and churches within the highest CNEL measurement zone. [SEIR, p. 5-19] Mitigation Measure MM-RBR-2 calls for coordination with Inglewood to identify residential land uses where acquisition and conversion to compatible uses is contemplated or deemed appropriate. [SEIR, p. 4-339] Acquisition of residences for the purpose of converting residential to more compatible uses, and thus avoiding noise impacts on affected minority communities, necessarily implies relocation of displaced residents of the acquired properties.

Further, Mitigation Measure RBR-1, which applies to all alternatives, proposes preparation of a Residential and Business Relocation Plan and expansion the current relocation program. [SEIR, p. 5-6] The SEIR's relocation objectives include informing Project area residential occupants [in Spanish and other languages] about matters such as relocation assistance and benefits, replacement housing and housing referrals, notices to vacate, displaced persons assistance, applications and claims for relocation benefits, evictions and property management, and grievance procedures for relocatees. [SEIR, pp. 5-6 - 5-7] In direct contradiction to RBR-1, however, Section 4.4.3.5.5.1 disclaims any residential relocation plans, and fails to mention, much less address, avoidance or minimization of relocation impacts on minority and low-income residents, as required by Federal Environmental Justice statutes.

Finally, Section 4.4.3.5.2 states that the environmental impacts of air quality under Alternatives A, B and C have not materially changed, but, that under Alternative D, airport activity would be focused in areas at the east side of the airport, resulting in greater emissions east of the airport [SEIR, p. 4-329]. Most of those effects would remain adverse following implementation of proposed mitigation measures. Specifically: minority and low-income populations may be more severely affected because they may be more susceptible to asthma and other chronic respiratory illnesses trigger by the high O₃ levels in the area; children within minority communities may be particularly susceptible to health effects of PM₁₀, ozone and NO₂, and thus may be more severely affected than other communities exposed to equivalent level of those pollutants; and children living in poverty who lack access to adequate health care may be especially at risk. [SEIR, p. 4-330]

Despite these acknowledged severe project impacts, and perhaps because of the further claim of the purported utility of proposed aggregate air quality mitigation measures, the SEIR fails to explore further minimization of specific effects, by feasible means such as committing to air condition homes and schools affected, see *Los Angeles Unified School District, supra*, 58 Cal.App.4th at 1029-30, or relocating impacted populations.

B. The SEIR's Proposal to Provide Job Benefits to Minority And/or Low-Income Communities Is Inadequate Where it Is Contingent on FAA Approval of the Use of Airport Revenues and Ignores the Projected Decrease in LAX Related Jobs under Alternative D.

DOT Order 5610.2 § 6.b.(2) requires that measures be proposed to provide offsetting benefits and opportunities to enhance communities, neighborhoods and individuals affected by DOT programs. The "Benefits" section [unnumbered] of the SEIR states that jobs are one of the economic benefits directly and indirectly attributable to LAX [p.4-339], and that LAX is working to create job recruitment, job training and job placement programs that will enable local youths and adults to more easily access jobs at and around LAX in the future. [SEIR, p. 4-339 - 4-340] However, the jobs related proposal is a house of cards where: (1) adoption and implementation of job recruitment, training and placement programs are subject to FAA approval of the use of airport revenue to fund such activities; and (2) even if use of airport revenues is approved for recruitment and job training, job placement under Alternative D will be difficult, where the SEIR acknowledges that Alternative D would have no meaningful contribution to job growth. [SEIR, p. 4-351]

The SEIR proposes to expand existing programs and create new programs at its Jobs Outreach Center which would be primarily focused on minority and/or low-income residents located east of LAX, including Inglewood. [SEIR, p. 4-340] Inglewood, as acknowledged in the SEIR is already disadvantaged with respect to employment at LAX, where only 2,304 (3.9%) of the 59,000 badged employees at LAX reside in Inglewood. [SEIR p. 4-339, fn. 100]. The

SEIR's job creation proposal contains some giant loopholes. For example, funding for the proposed jobs related programs is totally contingent upon FAA approval of diversion of airport revenues for that purpose. The SEIR contains no evidence that LAX has made application for FAA approval, provides no information to the public on the likelihood that FAA approval will be granted, and offers no alternative plan for funding jobs programs if the FAA does not approve the use of airport revenues for jobs programs. In other words, if the FAA does not approve the use of airport revenues, the entire jobs program collapses.

Even if funds are approved by the FAA, and local minority and low-income residents are trained in aviation related skills, job placement under Alternative D will be difficult, where Alternative D would result in a net decrease of approximately 23,000 jobs within a ten-mile radius of LAX by 2015 [SEIR, p. 4-339]. Alternative D is projected to support roughly the same level of employment as the No Action/No Project Alternative in 2015, and would have no meaningful contribution to job growth [SEIR, p. 4-351].

C. The SEIR's Conclusion That Construction Impacts Would Not Fall on Minority Communities Is Unsupported by Any Analysis of the Project's Cumulative Noise Effects.

The SEIR's conclusion that construction noise effects would not fall on minority and/or low-income communities [SEIR, p. 4-333] is unsupported by any analysis of the cumulative effects of the Projects's ground traffic, aircraft and construction noise on communities located east of LAX. In reaching that conclusion, the SEIR makes the erroneous assumption, as set forth in detail above, that road traffic and aircraft noise will drown out construction noise, and that construction noise impacts on Inglewood residents will therefore be less than significant. However, as also set forth in more detail above, the SEIR's reliance on this "ratio theory" to discount the effects of construction noise improperly masks the palpable adverse impacts of Project construction on communities to the east of the airport, particularly where Alternative D proposes more construction on the eastern portion of the airport, which, in turn, results in hitherto unanalyzed construction noise, air quality and traffic impacts.

D. No Effective Mitigation is Provided to Ameliorate the Project's Adverse Impacts.

Despite the SEIR's acknowledgment that the project will have a grossly disproportionate impact on minority communities, it contains few measures, and no certain, binding commitments to ameliorate impacts of construction or Project implementation on affected communities including Inglewood. Such measures should include, but not be limited to:

1. OPERATIONAL MITIGATION.

In addition to all other operational mitigation specified in the DEIR and SEIR, the Part 161 Application to the FAA should be expanded to provide that no operations shall take place

over Inglewood between the hours of 11:00 p.m. and 6:30 a.m.; and that where "over-water" operations are not feasible for reasons of wind, weather or other safety related conditions during those hours, operations will either be held in place, in the case of departures, or sent to other airports in the case of arrivals.

2. NOISE COMPATIBILITY PLANNING AND IMPLEMENTATION.

(a) COMPLETION AND EXPANSION OF RESIDENTIAL SOUND INSULATION PROGRAM - A firm, binding commitment to: (1) provide funding to complete the existing residential sound insulation program provided in the ANMP and MOU between Inglewood and Los Angeles; (2) expand that program to include residences in the 60 CNEL contour and the 94 dB SEL "awakening" contour as set forth in the SEIR; and (3) maintain 45 dB interior noise levels over time in all properties subject to the residential sound insulation program, including, but not limited to, replacement of equipment and improvements that malfunction due to age or environmental factors, or become obsolete due to increases in noise levels applicable to the properties.

(b) RELOCATION OF SCHOOLS - A firm, binding commitment, not contingent on the results of future studies, to relocate schools currently and newly impacted by noise resulting from the implementation of the project to sites specified by Inglewood;

(c) IMMEDIATE SOUND ATTENUATION OF ALL SCHOOLS, CHURCHES AND OTHER PUBLIC PLACES THAT CANNOT BE RELOCATED - A firm, binding commitment to sound attenuate, not contingent on further studies, all of the schools identified as impacted by the project in any way that cannot be relocated, as well as noise impacted churches and other public gathering places including medical and rehabilitation facilities;

(d) LOCATION OF A FLY AWAY FACILITY - A firm, binding commitment to locate a fly away facility at the proposed location of the corner of Prairie Avenue and Century Boulevard in Inglewood;

(e) ADDITIONAL ROAD AND STREET IMPROVEMENTS - A firm, binding commitment to improve streets used heavily for access to LAX and the new remote fly away facilities including, but not limited to, Century Boulevard, Manchester Boulevard, Arbor Vitae Street and Florence Avenue;

(f) GENERAL PLAN - Binding commitment to provide funding for the development of a General Plan for the City of Inglewood to supercede its currently outdated land use element, and enable Inglewood to plan compatibly with airport operations;

(i) CENTURY BOULEVARD SPECIFIC PLAN -

Development of a Specific Plan for the half mile length of Century Boulevard between La Cienega Boulevard and Inglewood Avenue in order to exploit its unique location to create a focused airport-patron environment predominantly composed of hotel and restaurants, with supportive retail and office uses, thus enhancing the primary portal into LAX from the freeway;

(ii) FUNDING FOR CENTURY BOULEVARD CORRIDOR IMPLEMENTATION PROJECT - A firm, binding commitment to provide funding to complete the major study and improvement design for the Century Boulevard corridor, particularly between La Cienega and Prairie Avenue, including conversion of currently noise impacted single and multi-family residential buildings to commercial uses;

(iii) BUSINESS PARKS - A firm, binding commitment to provide planning and development funds for business and industrial parks, consistent with the development study currently underway by HNTB and the recently completed economic impact analysis by Kosmont Partners, along Century Boulevard between I-405 and Prairie Avenue, with specific emphasis on the area closest to the new GTC;

(iv) PUBLIC PARKS, GOLF COURSE, NATURE CENTER - A firm, binding commitment to provide funding for conversion of incompatible residential and other uses, other than those redeveloped for commercial purposes to public parks, a municipal golf course, and/or nature center;

(v) BRANDING, SIGNAGE AND WAY FINDING - A firm, binding commitment to provide adequate signage for those accessing LAX and the amenities of the City of Inglewood including Hollywood Park and Daniel Freeman and Centinella Hospitals.

(vi) LIBRARIES - A firm, binding commitment to fund the replacement of libraries to be impacted by the project, and the expansion of Inglewood's library system to accommodate increased student populations;

(vii) YMCA - A firm, binding commitment to fund the replacement of the existing YMCA at 102nd Street and Prairie Avenue;

(viii) HEAD START CHILD DEVELOPMENT FACILITIES - A firm, binding commitment to fund the development of new childcare and education centers in compliance with the requirements of the new General Plan;

(ix) SENIOR CITIZEN HOUSING - a firm, binding commitment to fund new senior housing and assisted living communities consistent with the requirements of the new General Plan.

(g) PROVISION OF FUNDS FOR ACQUISITION AND RELOCATION - A firm, binding commitment to provide funding for the acquisition of all properties falling within any of the criteria of significant noise impact in the SEIR and of funding for relocation housing and expenses;

(h) JOB TRAINING - A firm, binding commitment to begin immediate training of Inglewood residents in: (a) construction related skills necessary to participate in the construction phase of the project; and (b) skills necessary to obtain long term employment at LAX, including, but not limited to, the creation of a new vocational school dedicated to preparing students for careers in aviation industries and emerging hi-tech industries of aviation maintenance, as required in concept by the MOU;

(i) FUNDS FOR JOB TRAINING - A firm, binding commitment to provide local funding for jobs training programs, either to augment Federal funds provided for training, or to fund the training program in its entirety if the FAA does not authorize the use of airport revenue for training purposes;

(j) MODIFICATION OF THE MOU - A firm, binding commitment to extend the MOU at least through the year 2015, concurrent with the implementation of the LAX Master Plan, including, but not limited to, the abrogation of the requirement to dedicate aviation easements; acknowledgment that easements as yet unrecorded will not be re-recorded at the expiration of the MOU, and the reconveyance of all easements previously recorded.

3. ADDITIONAL RESEARCH.

In addition to all other studies specified in the DEIR and SEIR, a study be conducted of the incidence of air pollutants, resulting from aircraft operations, traffic and other sources related to LAX, and their health effects, both generally and on residences of the City of Inglewood specifically.

November 4, 2003

Page 42

In summary, while Inglewood appreciates the efforts that have been made by Los Angeles to cope with the difficult problems of limitation of airport operations and environmental compatibility with surrounding communities, more clearly needs to be done to remedy the problems that fall squarely on the shoulders of Inglewood and particularly its low income and minority residents. Inglewood looks forward to continuing its ongoing cooperation with Los Angeles in fostering both economic growth and improved quality of life for all citizens of Los Angeles and its neighboring communities.

Inglewood thanks Los Angeles for this opportunity to comment.

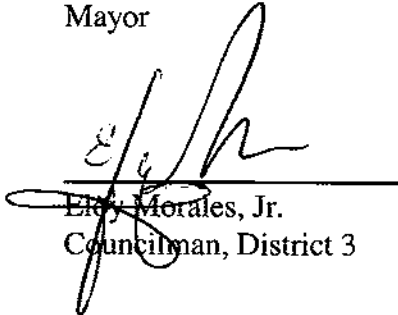

Sincerely,

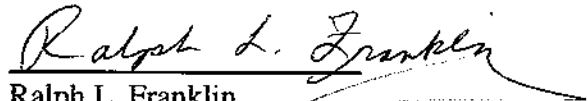

Roosevelt F. Dorn

DRAFT ENVIRONMENTAL IMPACT STATEMENT/
ENVIRONMENTAL IMPACT REPORT,
LOS ANGELES INTERNATIONAL AIRPORT
PROPOSED MASTER PLAN IMPROVEMENTS -
COMMENTS RE: ALTERNATIVES A THROUGH C

The following constitutes comments, pursuant to the requirements of the California Environmental Quality Act, Public Resources Code § 21000, et seq., (“CEQA”) and the National Environmental Policy Act, 42 U.S.C. § 4321, et seq., (“NEPA”), concerning the Draft Environmental Impact Statement/Environmental Impact Report (“Draft EIS/EIR”) for the Los Angeles International Airport (“Airport”) Proposed Master Plan Improvements (“Project”), prepared jointly by the Federal Aviation Administration (“FAA”) and the City of Los Angeles (“Los Angeles”),¹ and Alternatives A through C presented therein.

The issues raised by these comments fall into seven general categories, although they are not limited only to those categories:

- (I) the baseline used in the Draft EIS/EIR, against which the various environmental impacts of the Project are compared, is not properly designated;
- (II) the discussion of the Project’s surface traffic impacts is misleading;
- (III) the noise impacts of the Project are inadequately addressed;
- (IV) the potential air quality impacts of the Project are not fully disclosed;
- (V) the Draft EIS/EIR does not explore all reasonable alternatives, and, thus, paves the way for its ultimate conclusion that expansion of the Airport’s airside and groundside facilities are the sole way to meet future demand;
- (VI) the LAX Master Plan and Draft EIS/EIR fail to satisfy applicable law because they do not conform to other relevant plans;

¹ The FAA and Los Angeles shall, for the remainder of these comments, be referred to collectively as “Project Proponents”.

(VII) the Draft EIS/EIR fails to adequately specify mitigation measures or methods to enforce them;

(VIII) the recently articulated project goal of increasing safety obscures the Project's clear capacity-enhancing purpose. As a result of these defects, the Draft EIS/EIR cannot meet the high standards of disclosure that are the gravamen of both CEQA and NEPA;

(IX) the Draft EIS/EIR does not meet environmental justice requirements; and

(X) the Draft EIS/EIR fails to adequately account for human health risks.

I. THE DRAFT EIS/EIR DOES NOT PROPERLY DESIGNATE THE BASELINE FOR ANALYSIS.²

The specification of a baseline for comparison with Project impacts is a critical component of analysis under CEQA, because without an accurate specification of the baseline, "analysis of impacts, mitigation measures and project alternatives becomes impossible." County of Amador v. El Dorado County Water Agency, 76 Cal.App.4th 931, 953 (1999). A central concept of CEQA is that "a baseline figure must represent an environmental condition existing on the property prior to the project." Save Our Peninsula Committee, et al. v. Monterey County Board of Supervisors, et al., 87 Cal.App.4th 99, 124 (2001). The regulations implementing CEQA, 14 Cal. Code Regs. § 15000, et seq., ("CEQA Guidelines") are specific as to the definition of "prior to the project":

"An environmental impact report must include a description of the physical environmental conditions in the vicinity of the project, as they exist at the time the Notice of Preparation is published, or, if no Notice of Preparation is published, at the time the environmental analysis is commenced . . . This environmental setting will normally constitute the baseline physical conditions by which a lead agency determines whether an impact is significant." CEQA Guidelines § 15125(a).

² Later sections II, III and IV more fully discuss the pitfalls arising from the use of the three separate and distinct baseline assumptions used in that analysis; Environmental Baseline, Adjusted Environmental Baseline, No-Project/No-Action.

While the courts have taken the position that the “date for establishing a baseline cannot be a rigid one”, Save Our Peninsula Committee, *supra*, 87 Cal.App.4th at 125, they have also held unequivocally that “an EIR must focus on impacts to the existing environment, not hypothetical situations”, County of Amador, *supra*, 76 Cal.App.4th at 955. The baseline for analysis in the Draft EIS/EIR does not meet these tests.

A. The Draft EIS/EIR’s Base Year Does Not Reflect the Physical Conditions on the Project at the Time of the Publication of its Notice of Preparation.

The Airport Master Plan, November, 2000, Technical Analysis (“Master Plan”) is the basis of the analysis contained in the Draft EIS/EIR (Master Plan, Preface, page i). The analyses contained in Master Plan, Chapter II, Existing Conditions Working Paper, 4/19/96, use data from the base year 1994 (see, e.g., § 2.3.1, page II-2.1, re: Annual Weather Conditions; Figure II-2.17, page II-2.53, re: Design Day Hourly Distribution of Operations and Tables following). The Notice of Preparation, however, was published in July, 1997 (Draft EIS/EIR, page ES-2), almost three years after the conditions reflected in the original Master Plan data and analysis. Courts have consistently taken the position that a baseline should not “be set a number of years earlier than the commencement of the current project”. Save Our Peninsula Committee, *supra*, 87 Cal.App.4th at 127.

Moreover, the Master Plan and Draft EIS/EIR contain multiple inconsistent base years such that it is impossible for the public to ascertain which base year is used for a given purpose. On the one hand, the Draft EIS/EIR (page ES-2) states that the environmental analysis normally describes existing conditions as of the July, 1997 date on which the Notice of Preparation was published (even though none of the data in the Master Plan upon which the Draft EIS/EIR is based reflects a 1997 origin). On the other hand, the Draft EIS/EIR states that, where a full year’s worth of data is needed, data from 1996 is used (see, e.g., Draft EIS/EIR Technical Report on Surface Traffic), and sometimes earlier years [unspecified], and sometimes even data from the later years 1999 and 2000 (even though these latter are more than two years after the publication of the Notice of Preparation). Additionally, the Master Plan is unclear as to whether 1994 or 1995 data is used. Finally, different base years are used for different components of the analysis, e.g., 1996 for surface traffic and noise, 2000 for water resources.

Such selective shifting of baselines has substantive consequences. For example, the use of a 1994 (or even 1996) baseline in analysis of aircraft noise impacts artificially elevates the baseline for analysis by incorporating noise from the larger numbers of Stage 2 aircraft in the fleet in 1994/96. These aircraft were totally phased out of the United States fleet by the year 2000. Further, the use of a 1994 (or 1996) baseline year in the air quality analysis potentially overstates the baseline level of criteria pollutants in the L.A. region which has since come into attainment for all criteria pollutants except Ozone and Particulate Matter.³ In short, the

³ The Draft EIS/EIR also states that its use of earlier years results in a more “conservative” analysis, because there were fewer passengers and operations in earlier years, and, thus, less noise and fewer emissions to compare against those generated by the Project. This

nonspecificity of both the Master Plan and Draft EIS/EIR with respect to the base year for analysis renders the results of their analyses questionable.

B. The Master Plan and Draft EIS/EIR Baseline Analyses Are Based On Incomplete and/or Inaccurate Data.

The Master Plan defines the capacity of the Airport's existing airside facilities as "the number of aircraft operations, arrivals and departures, that the Airport can accommodate with a reasonable amount of aircraft delay." (Master Plan, § 2, page II-2.1) The correct determination of existing airside capacity is critical to identification of the Airport's potential to accommodate future air traffic demand and plan future airport's development. (Master Plan, Chapter 2, page II-2.1) Various independent variables are used in the modeling of existing airport capacity, including, but not limited to: (1) runway operating configurations; (2) noise abatement procedures; (3) airspace operating assumptions; and (4) airfield operating assumptions. (Master Plan, § 2.3, page II-2.21) Delay is also apparently a contributing variable. The relationships within the model are such that, if the definition of a given variable, or the value assigned to it, are questionable, the capacity determination resulting from the model is prejudiced.

Here, even if, for argument's sake, the Draft EIS/EIR had specifically and accurately designated a base year, critical data used in the Master Plan baseline demand/capacity/delay analysis is incomplete or in some cases inaccurate.

As a threshold matter, the Master Plan demand/capacity/delay analysis is predicated on Aircraft Communications, Addressing and Reporting System ("ACARS"), and Official Airline Guide ("OAG") data sources. These two data sources exaggerate, or, inaccurately characterize, true (airport capacity related) delay. The Master Plan defines delay as "the difference between the actual time it takes an aircraft to perform an arrival or departure and the normal time it would take to perform the same operation with no interference from other aircraft." (Master Plan, § 2.1, page II-2.2) ACARS data is generated by the airlines, and is based on activities such as push back, parking at the gate, or opening or closing cabin doors. ACARS data includes information about on-time performance, based on the arrival and departure times developed by each airline for each segment of flight. Since the data is airline-generated, airline definitions of delay are automatically built into the report.⁴

claim is inaccurate at least with respect to noise and air quality analyses as set forth below. In any event, it does not account for the opposite effect of using later years 1999/2000 as the baseline, which would, by the logic used in the Draft EIS/EIR, artificially elevate the baseline and, consequently minimize the environmental impacts of the Project. As neither the Master Plan nor Draft EIS/EIR are specific as to the distribution of various baseline years throughout the analysis, it is impossible to ascertain the degree of distortion that may have occurred through the use of these alternate baselines.

⁴ When an aircraft pushes back from the gate or closes the cabin door, the aircraft could be late for a variety of reasons. Many delays are due to factors that are airline-controllable

such as late boarding of passengers, customer service delays, maintenance delays, late arriving equipment, catering, fueling, baggage and the unavailability of crew members, to name but a few. Other types of delay would be attributable to airport, runway or taxiway design, airport acceptance rates, airport construction, noise abatement regulations, air traffic control restrictions and weather. These items are also introduced and incorporated into the ACARS report as a delay factor.

Further, the OAG is published for the express purpose of identifying the arrival and departure times of various airlines. When the airlines set up their schedules, they factor in the average delay for each leg of flight between city pairs. Thus, the OAG also builds delay into the departure and arrival times based on each airline's historical data and operating experience for each flight segment.

In summary, ACARS data is not original source data but is the product of third party intervention. It is manipulated by various airline functionaries before a final report is released. Similarly, OAG data is manipulated to include delay not after, but before the fact. Therefore, because both sources of data already include a delay factor, their use in the Master Plan's modeling, as set forth below, is likely to cause a double counting of delay.⁵

Instead of ACARS or OAG data, the Master Plan should have relied on radar data. Radar data is a memorialization of the movement of arriving aircraft from a specified distance outside the terminal control area until touchdown and, conversely, for departing aircraft, from the aircraft's lift-off from the runway to the same distance outside the airport's control area. Every operation is tracked in real time without the intervention of third party interpretation, manipulation, or extraneous factors, unrelated to the operational capacity of airport infrastructure.

The effects of this confounding of substantive with non-substantive delay factors are reflected in the Master Plan's modeling of demand/capacity/delay. The FAA's Simulation Model ("SIMMOD"), Version 2.1, was apparently used in the Master Plan's demand/capacity/delay analysis. SIMMOD simulates the movement of arriving and departing aircraft from their entry/exit into the Los Angeles Terminal Air Traffic Airspace through approach and landing phase, or taxi and takeoff, to their exit from the terminal air traffic airspace. Proper calibration of SIMMOD is essential since the resulting statistics depend upon the data used to develop the baseline assumptions and operating instructions for the model. In this case, ACARS and OAG data were used to calibrate SIMMOD. Because of the potential double counting inherent in these data sources, and the consequent exaggeration of delay in the model, the principal conclusion that is drawn from SIMMOD is that the only way to remedy delay is to build additional airport infrastructure. The most obvious flaw of such an analysis is that it eliminates, at the outset, opportunities to gain efficiency through improvements in

⁵ In addition, the Master Plan analysis relies on numerous sources other than ACARS or OAG data including personal observations, a small sampling of users and an unique determination of aircraft speeds and routes, none of which is suitable, let alone optimal, for developing baseline analyses or formulating assumptions. (See, e.g., Master Plan, § 2.1.3, pages II-2.5 - II-2.6)

operating practices and minor modifications to the air traffic system. Thus, what seems like a relatively minor data collection/designation problem pervades the demand/capacity/delay modeling upon which the Draft EIS/EIR's environmental analysis is based, and subtly biases the results.

C. The Draft EIS/EIR is Based on Implausible Modeling Assumptions.

The accuracy of SIMMOD's results depends on an accurate "description" of the "airport's operating environment". (Master Plan, § 2.1, page II-2.2) Both the Master Plan and Draft EIS/EIR acknowledge that the "description" is made up not merely of data purporting to represent actual current conditions, but also assumptions arising from that data (see, e.g., Master Plan, § 2, page II-2.1). Therefore, to the extent data and assumptions are incorrect or incomplete, so too will be the results of the model. In addition to the data problems specified above, SIMMOD, as used in the Master Plan, incorporates implausible, or biased, assumptions which, in turn, call into question the integrity of its output.

1. Assumptions Concerning Aircraft Delay Are Unexplained and Unsupported.

The Master Plan's (and Draft EIS/EIR's) definition and description of the delays at the existing (pre-Project) Airport are based on consultants' opinions and not on factual information. First, while the Master Plan acknowledges that "a standard definition of acceptable delay is not used in the industry" (Master Plan, § 2.1.3, page II-2.5), it then concludes that "delay levels of six to ten minutes indicate the need for additional facilities"; that "as average aircraft delay increases above six minutes, passengers tend to perceive service reliability problems"; "as delay approaches ten minutes per operation, further increases in demand are limited", and, "flight cancellations were assumed when delays exceed 20 minutes per average annual aircraft operation." (Master Plan, § 2.1.3, pages II-2.5 - II-2.6) These assumptions are apparently based on information derived from prior studies by the Master Plan consultants at airports other than Los Angeles, in years as early as 1988. In other words, the delay standards relied upon in the Master Plan are based on outdated data concerning potentially irrelevant subject airports. All of these have unique characteristics that may have influenced creation or perception of delay, and none of them are discussed in the Master Plan or Draft EIS/EIR.

Further, these unsupported assumptions do not reflect an understanding of the diverse ways in which delay is determined by the airlines, Air Traffic Control and the Department of Transportation. First, a typical airline will develop performance criteria for each phase of flight based on company goals and performance percentages, including arrival and departure delay. Airlines use "zero variance" as a standard for "on time" performance (i.e., zero difference between arrival and/or departure times and published schedules). The percentage goal for each activity will be based on the level of performance the airline hopes to, or, in some cases, must attain in order to remain competitive. Some airlines track on time performance plus five minutes and most will track on time performance plus 14 minutes.

FAA Air Traffic Control, on the other hand, computes delay based on actual delay time en route. An arriving aircraft is considered delayed only if the aircraft is held en route to the destination for 15 minutes or more at any given moment during the flight. It is possible that these aircraft could be held at more than one interval during a flight. However, if each holding period does not exceed the 15 minute threshold, no delay is recorded, even though the total delay might well be in excess of 15 minutes. Further, inbound delay is kept separate from outbound delay. A departing aircraft is not counted as delayed until: (1) the average taxi time for the airport; (2) the time from the gate to the runway; and (3) 15 minutes have cumulatively elapsed. Air Traffic Control delays do not consider airline schedules or internally generated delays in their reporting system. The majority of Air Traffic Control delays are as a result of weather and not system capacity. Finally, the Department of Transportation grades airline performance on the time of arrival at the destination airport within 14 minutes of the scheduled arrival time. The Master Plan utilizes none of those benchmarks. Thus, the Master Plan fails to adequately explain the basis for its demand/capacity/delay analysis.

2. The Master Plan's Assumptions Concerning Turboprop Operations are Manifestly Inaccurate.

Referring to its analysis of existing noise abatement procedures as they pertain to the creation or maintenance of demand/capacity/delay, the Master Plan states that "based on actual information obtained by the Los Angeles Noise Management Bureau, turboprop departures were permitted to turn slightly earlier than jet departures at the Airport VOR, which is located between runways 7L and 7R, west of Pershing Drive" (Master Plan, § 2.3.3, page II-2.31). In addition, Figures II-2.11 and II-2.12 indicate that, when the Airport is operating on a west flow, turboprop aircraft turn at the VOR.

These representations are inaccurate and lead to incorrect assumptions about flight paths. In fact, if such a turn were permitted, it would occur prior to the shoreline, contrary to current noise abatement procedures. Turning the turboprops early allows faster aircraft to depart behind the turboprops at a more accelerated rate than is currently allowed, thus allowing more aircraft to depart in a given interval. The results of this inaccurate assumption are that: (1) the baseline departure capacity is artificially elevated to a level higher than would be realized had actual air traffic data been used and the noise abatement procedures modeled as they are actually used; and (2) turboprops, as depicted in the Master Plan and Draft EIS/EIR, are directed over noise sensitive areas not previously overflown, and, as a result, elevate the baseline noise levels, thereby concomitantly reducing the apparent noise impacts of the Project.

3. The Master Plan's Flight Schedule Assumptions Are Outdated.

The Master Plan reports the results of a SIMMOD analysis conducted in 1994, using 1994 data and 1994 assumptions. In addition to this obsolete data, the ACARS data upon which the SIMMOD analysis is based includes less than 51% of commercial operations and more than

46% of the total operations in the design day flight schedule. As: (1) operational configurations long pre-date the commencement of the environmental process; (2) current schedules were not used (although available), the assumptions concerning a typical day's traffic are substantially unsupported; and (3) not all of the aircraft operators were considered, the assumptions concerning a typical day's traffic are substantially unsupported.

4. The Master Plan's Fleet Mix Assumptions are Inaccurate.

The Master Plan relies on a fleet mix distribution derived from "August 11, 1994 OAG, NMB Do Daily Operations Records and LADOA 1994 Monthly Air Traffic Volumes" (Master Plan, Table II-2.16, page II-2.58). This 1994 fleet mix distribution is outdated and, thus, inadequate for use in SIMMOD. Specifically, it includes a large number of Stage 2 aircraft which are no longer in operation at the Airport. Not only are Stage 2 aircraft noisier, but they have different emissions characteristics from the newer high bypass ratio, Stage 3 aircraft. If a more recent base year had been selected, the proportion of Stage 2 aircraft would have been smaller, and the noise baseline lower, and, thus, more accurate.

5. The Master Plan's Assumptions Concerning Aircraft Speed Are Inaccurate.

The Master Plan's assumptions concerning aircraft speeds were apparently inflated to fit the underlying assumption of unconstrained aircraft flows. The Master Plan model calls for all aircraft to operate at the same constant air speed before proceeding to the Airport and landing. The model further assumes that all aircraft exit the runway at the same point and within the same amount of time in order to reach the modeled flow rate. In actual conditions, the speeds of the aircraft vary, with high airspeed greatly reduced as the aircraft approaches the airport. Nor would all aircraft exit the runway at the same location. In short, this assumption of high constant speed will have an as yet unascertained impact on the model's results but would tend to overstate capacity of the existing facility, and, thus, the baseline for comparison with the Project's improvements.

D. The Master Plan's Model Omits Critical Variables.

Another crucial issue revolves around variables the Master Plan fails to include in its model. Specifically these include: (1) the capacity of the airspace beyond the Airport Terminal Control Area ("TRACON"); and (2) gate capacity for future scenarios.

1. The Master Plan Should Have Considered Airspace Capacity Beyond The Airport's Terminal Area Airspace.

According to the Master Plan, airspace considerations were limited to entry (and exit) from the Airport's TRACON airspace. (Master Plan, § 2.1.1, page II-2.3) The failure to consider airspace capacity beyond that point is a material omission from the analysis. This is

because the majority of aircraft delays are absorbed in the en route environment before an aircraft arrives in TRACON airspace. By modeling only the terminal area, the results of the model are skewed for both arriving and departing aircraft. For departing aircraft, if the model does not consider the inherent constraints of the en route air traffic system, including differences in aircraft performance and the impacts of other air traffic transiting the area for other airports, the departure flow pictured in the model will remain unconstrained and aircraft can take off at a constant, predetermined rate. When reaching the boundary, the aircraft are dropped from the scenario, and the model does not further consider constraints of the en route system which naturally impact the TRACON airspace. Unfortunately, this unconstrained flow scenario is not normally possible in today's complex air traffic control system.

Similar problems exist in modeling arrivals without consideration of airspace outside the TRACON. Inbound aircraft are assumed, in the Master Plan model, to be at the entry point of terminal airspace when required by the model. Aircraft proceed inbound at a set speed, reduce speed at a predetermined point, land and proceed unimpeded to their gate. This is not a reasonable representation of a typical aircraft arrival. In fact, there is almost no likelihood that aircraft can be delivered to the terminal inbound fix at a rate consistent with the model's assumptions.

Instead, the Master Plan's arrival model appears to have been developed to insure that an arriving aircraft would be at the inbound fix at the specific time required in order to maximize the arrival rate for the airport. Although Air Traffic Control consistently tries to keep the aircraft sequenced as closely as possible "intrail", it is not possible to consistently space aircraft a set distance apart for extended periods of time. The availability of aircraft to fit into the sequence, aircraft speeds, the mix of large and small aircraft, a lack of demand, aircraft deviations due to weather, intrail restrictions though an en route sector or intrail restrictions required for an airport approach control facility and other variables cause the in trail spacing of arrival aircraft to be inconsistent. As a result of these and many other factors, there is unused capacity in each of these arrival sequences. In summary, the Master Plan's failure to adequately consider constraining factors outside the TRACON airspace calls into question the validity of the model's result.

2. The Master Plan Should Have Modeled Gate Capacity.

The Master Plan did not include in its modeling aircraft gate operations for future activity levels, allegedly because of the inability of the existing gate facilities to accommodate the higher activity levels.⁶ (Master Plan, § 2.5.3, page II-2.104) The Master Plan disclaims the importance of this omission ["The inability to model gate operations in detail does not impact the results of

⁶ Performance measures contained in the Master Plan, § 2.5.1, include "outbound ground delay" which, in turn, appear to include gate related variables such as "gate push-back delay". This performance measure was apparently used in the modeling of existing gate operations but not future ones. (Master Plan, § 2.5.1, page II-2.97)

the airside capacity analysis since at higher activity levels the runway system tends to be the primary constraint . . .” Master Plan, § 2.5.3, page II-2.110]. The Master Plan is in error.

If an aircraft cannot get to the gate unimpeded, the resulting delay must be factored into the analysis. In the Master Plan, taxi patterns are consistent and aircraft are dropped from the model when they reach the gate area. The model does not capture any delays in the gate area or any delays that might occur in reaching the gate due to congestion on the ramp. The same is true for departing aircraft. If a departing aircraft cannot leave the gate due to inbound traffic or other traffic in the gate area, the departure demand at the airport may not be as regular as is assumed in the Master Plan’s model.

The importance of this omission is that it precludes development of a clear picture of the delay reduction, and consequent capacity enhancing, attributes of the Project. Without estimation of the potential groundside/terminal structure constraints on operations (capacity), the actual delay reducing, and capacity enhancing, benefits of the Project as a whole cannot be accurately ascertained.

3. The Master Plan Should Have Considered Currently Implemented Air Traffic Procedures.

While the Master Plan acknowledges the existence of the current Dual Civet Arrival procedure, it fails to analyze its delay reducing, or consequent capacity enhancing efficiencies. The procedure is mentioned, then drops off the “radar” screen. The Dual Civet Arrivals, however, have so greatly reduced arrival delay at the Airport that no national delay program for the airport has been established since the procedure’s implementation. Ignoring the impacts of Dual Civet Arrivals results in an exaggeration of existing delay and a consequent exaggeration of the Project’s delay reducing, and capacity enhancing benefits.

E. Demand, as Defined in the Master Plan, is an Identity with Capacity.

Inaccurate data and assumptions are not alone in influencing the outcome of a modeling effort. Inadequate specification of a variable may also lead to an unrepresentative result. In this case, the independent variable, demand, as defined, is not independent but is virtually synonymous with, or surrogate for, the dependent variable, capacity. Thus, the demand variable has an interactive relationship with the dependent variable which influences the model’s outcome in significant ways.

For example, the Master Plan defines aircraft demand as “a 24-hour flight schedule representative of design day activity.” (Master Plan, § 2.1.2, page II-2.3) The “24-hour flight schedule” definition is almost identical to the definition of “capacity”, “the number of aircraft operations, arrivals and departures, that the Airport can accommodate with a reasonable amount of aircraft delay.” (Master Plan, § 2, page II-2.1) The two variables, therefore, vary together, i.e., as “capacity” increases, “demand” will also increase, rendering demand useless as a

predictor of capacity. The precise degree in which the interaction of the independent and dependent variables in the model affect the analysis cannot be ascertained at this point without re-running SIMMOD. Suffice it to say that a new surrogate for demand, derived, for example, from airline market surveys, or annual enplanements, is necessary to insure the integrity of the model's results.

II. THE DRAFT EIS/EIR DOES NOT FULLY ANALYZE THE PROJECT'S OFF-AIRPORT SURFACE TRAFFIC IMPACTS.

While the Draft EIS/EIR's off airport surface traffic analysis adequately depicts some aspects of the Project's surface traffic generation potential, it is notably deficient in the following ways: (1) the use of the Adjusted Environmental Baseline for comparison with the Project's surface traffic impacts creates a misleading picture of the magnitude of those impacts; (2) the Draft EIS/EIR improperly equates the direct and cumulative impacts of surface traffic; (3) the Draft EIS/EIR provides inadequate information regarding the Northside/Westchester Southside Project; (4) the Draft EIS/EIR transportation planning horizon is improperly attenuated; and (5) the Draft EIS/EIR lacks a mitigation monitoring program detailing implementation of mitigation measures for the impacts of surface traffic.

A. The Use of the Adjusted Environmental Baseline for Comparison With the Project's Surface Traffic Impacts is Misleading.

Three scenarios were used as baselines against which to evaluate the surface traffic effects of the proposed Master Plan improvements: (1) Environmental Baseline; (2) Adjusted Environmental Baseline; and (3) the No-Project/No-Action alternative. The Environmental Baseline is the existing condition pre-project. It includes existing roadways and land uses, and the current airport configuration. The year used in this baseline changed during the development of the Master Plan. At the initiation of the Master Plan process, the baseline year used was 1994. Information is reported in different Master Plan sections for 1994 and 1995. For the third iteration of the Master Plan, the baseline became 1996. The technical reports for the Draft EIS/EIR used 1996.

The Adjusted Environmental Baseline uses the current airport configuration but assumes that future off airport roadways and land uses already in the pipeline will be completed (see Section B.1 below). As with the Environmental Baseline, the definition of Adjusted Environmental Baseline changed with the development of the Master Plan. The existing condition section of the Master Plan (Chapter IV, Section 7) used horizon years of 2000 to 2015. The "constrained" alternatives section (Chapter V, Section 3) used the years 2005 and 2015. Finally, the No-Action/No-Project Alternative is the converse of the Adjusted Environmental Baseline and assumes that off-airport development will remain constant, but currently approved airport projects will be completed.

There are at least two issues of importance raised by reliance on the Adjusted Environmental Baseline: (1) accuracy of the Adjusted Environmental Baseline and its resulting projections; and (2) applicability of the Adjusted Environmental Baseline to the environmental impact analysis.

1. The Uncertain Definition of the Adjusted Environmental Baseline Makes the Results of its Comparison With Project Impacts Questionable.

The initial question about the Adjusted Environmental Baseline is the accuracy of the definition of “Existing Condition/Environmental Baseline” on which it is purportedly based. There are significant differences between the 1995 data concerning the “Existing Condition/Environmental Baseline” contained in the proposed Master Plan and the 1996 data contained in the Draft EIS/EIR. A comparison of Master Plan, Table II-7.2 and Draft EIS/EIR, Table 4.3.2-24, for the a.m. peak hour, shows changes in the “Existing Conditions/Environmental Baseline” between 1995 and 1996. As illustrated in the following Table, some intersections got significantly better and some significantly worse. In all but one case, the difference in V/C ratios between 1995 and 1996 exceeds thresholds used for determining significance in the Draft EIS/EIR.

Intersection	Master Plan Table II 7.2 1995 V/C*	EIS/EIR Table 4.3.2-24 1996 V/C	V/C Difference
Aviation/El Segundo	0.981(E)	0.835(D)	-.146
Aviation/Rosecrans	0.915(E)	1.121(F)	.206
Highland/Rosecrans	0.714(C)	1.069(F)	.335
Sepulveda/El Segundo	0.840(D)	0.869(D)	.029
Sepulveda/Mariposa	0.776(C)	0.730(C)	-.046
Sepulveda/Rosecrans	1.238(F)	1.220(F)	-.018
Vista Del Mar/Grand	0.755(C)	0.749(C)	-.006
Vista Del Mar/Imperial	0.821(D)	0.465(A)	-.356

* In Master Plan Table II 7.2 the first column heading is apparently mislabeled

Moreover, the “adjustments” to the “Existing Conditions/Environmental Baseline” involved adding additional roadways and additional traffic to the system based on anticipated projects. The definitions of these “adjustments” is not consistent within the Draft EIS/EIR, or between it and the Master Plan. For example, the Draft EIS/EIR states that: “A list of approved development projects were developed . . . (Draft EIS/EIR, page 4-279)” [Emphasis added.] The traffic technical report on which the Draft EIS/EIR is based states: “A list of planned development projects was developed . . .” (Technical Report, § 3b, page 2-3)” [Emphasis added.] Master Plan, Table IV-8.3; Master Plan, Chapter V, Appendix L; and Technical Report,

3b, Table 2-3, present projected regional roadway improvements. Master Plan, Chapter V, Section 2.6 indicates that the future roadway network used in the analysis includes those projects “. . . currently funded and approved or which have a high probability for completion by 2015 . . .” Clearly, the distinction between “approved” and “planned” projects is critical to a functional definition of Adjusted Environmental Baseline. The baseline will be set much higher (and the consequent relationship of the Adjusted Environmental Baseline with the Project’s impacts much lower) if all planned projects are included in addition to all approved projects.

Finally, Chapter IV of the Master Plan (Table VI-8.1, page IV-8.5) provides a “preliminary list of related projects” that differs from the list presented in Table 2.2 of the Draft EIS/EIR Traffic Technical Report, 3b. While differences are to be expected between the 1996 version of the Master Plan and the Updated 2000 version of the Traffic Technical Report, one difference may be more crucial than others - the projected size and resulting traffic impact of the Playa Vista Project. For example, according to the Master Plan, Table IV-8.1, the Playa Vista Project will contain 13,156 single-family units and 8,262 multi-family units. Master Plan, Chapter V, Appendix L, and the Draft EIS/EIR Traffic Technical Report specifies 13,085 multi-family units and no single-family units for the same Project. There is no explanation for the change, nor any reference to the source of either number. The difference is crucial because the traffic analysis assumed three people for each single-family home, and only two for each multi-family residence. The change therefore results in a significant diminution in traffic if the latter multi-family numbers are correct. Considering the potential of over 13,000 housing units for traffic generation, a complete explanation is needed to render the Draft EIS/EIR surface traffic analysis.

2. The Applicability of the Adjusted Environmental Baseline to the Draft EIS/EIR Traffic Analysis is Questionable.

As set forth above, the off airport surface traffic analysis in the Draft EIS/EIR uses the Adjusted Environmental Baseline as “the basis of comparison under CEQA for future mitigation for the three build alternatives” (Draft EIS/EIR, page 4-276). The Adjusted Environmental Baseline reflects projected conditions in the years 2005 and 2015 with off airport land use activities completed and regional circulation improvements in place, but without any increased use of the airport. This approach minimizes the potential direct impact from the adoption of the proposed Master Plan because: (1) the future traffic volumes without the Project increase thereby reducing the proportional effect of the added airport traffic from the Project and (2) additional circulation system improvements provide additional capacity. While it is reasonable to assess particular impacts at the time at which they might occur, relying on this approach requires assurances that the projected circulation improvements will actually be in place. No such assurances are provided in the Draft EIS/EIR.

The Off Airport Technical Report lists circulation system improvements that were included in the modeling process. This listing provides an indication of when certain improvements are anticipated. Without these improvements, the circulation system for the

Adjusted Environmental Baseline would, apparently, be the same as for the 1996 condition, and many more intersections and roadway segments would be subject to significant adverse impacts as a result of the proposed Master Plan. It is important, therefore, that the Draft EIS/EIR traffic analysis include projected phasing of the anticipated improvements relative to the additional traffic resulting from airport use. This should include a discussion of the phasing of airport improvements as they pertain to traffic generation with respect to the circulation improvements used in the Adjusted Environmental Baseline. Limitations should be placed on airport traffic generation if anticipated circulation improvements off-airport do not occur. Once the Adjusted Environmental Baseline is accepted as accurate and the conditions to achieve it are assured, the next issue concerns the significance of surface traffic impacts and the mitigation measures needed to reduce those impacts.

B. The Direct and Cumulative Impacts of Surface Traffic Are Improperly Equated.

The surface traffic analysis uses traffic volumes from airport and non-airport projects. (See, e.g., Master Plan § 2.6.2, page V-2.279). Therefore, it is at least partially a cumulative impact analysis.⁷ Because the surface traffic analysis is based on cumulative traffic volumes, the significance of the direct impacts and the cumulative impacts are equated. However, the use of the Adjusted Environmental Baseline makes this equation between direct and indirect effects inappropriate. While comparing the Project to the adjusted future conditions may be appropriate for assessing direct impacts, the cumulative impact is the impact of all traffic relative to the existing condition, not expected future conditions as contained in the Adjusted Environmental Baseline.

The result of this improper equation of direct and indirect effects is material. The following Table (derived from Draft EIS/EIR, Table 4.3.2-24) for the a.m. peak hour illustrates the problem. The reported change in congestion between the existing conditions and Alternative C, the preferred project alternative, is often significant, while the comparison of Alternative C with the Adjusted Environmental Baseline (which incorporates future conditions) is not.

⁷ “The cumulative impact from several projects is the change in the environment which results from the incremental impact of the Project when added to other closely related past, present, and reasonably foreseeable probable future projects.” (CEQA Guidelines, § 15355(b))

Intersection ⁸	Existing Adjusted		Alternative C	Difference	Difference
	V/C(LOS)	Baseline (w/mit) V/C(LOS)	V/C(LOS)	(w) Existing	(w) Adjusted
Aviation/El Segundo	0.835(D)	1.097(F)	0.865(F)*

* Apparent error in Table 4.3.2-24 of the EIS/EIR (page 4-340)

Using this concept of the Adjusted Environmental Baseline, the result is that the cumulative impacts of the Project are often significant and not mitigated even when the Project's direct effects have been.⁹

C. The Draft EIS/EIR Inadequately Documents the Northside/Westchester Southside Project.

The Draft EIS/EIR's impact analysis for off airport surface traffic is dependent upon the assumption that there will be a substantial reduction in the number of trips generated from the Northside Project. By "reconstituting" the Northside Project into the Westchester Southside Project, the Draft EIS/EIR projects that there will be a significant decrease in collateral trips with the adoption of the proposed Master Plan.

⁸ Change in V/C Rates of .01 defines significant impact for intersections at LOS F (Draft EIS/EIR, p. 4-291).

⁹ Note that if the comparison had been between Alternative C and the No-Project/No-Action Alternative, the difference would have been even greater, as the No-Project/No-Action Alternative provides for on-airport, potentially capacity-enhancing, improvements, but not off-airport surface traffic impact mitigation.

The source of the collateral trip reduction is the change in the land use for the Northside Project and Continental City Project. Attachment A of Technical Report 3b provides the basis for the reduction in collateral trips.

	AM PEAK			PM PEAK		
	Adjusted Baseline	No Project	Alternative C	Adjusted Baseline	No Project	Alternative C
Northside	0	7,217	3,922	0	7,131	4,423
Continental City	0	5,323	0	0	5,348	0
Manchester Square	0	0	212	0	0	233
Total	0	12,540	4,134	0	12,479	4,656

The issue here is the same as that concerning the Adjusted Environmental Baseline, i.e., the actions needed to insure that the reduction is achieved. The principal question is what specific discretionary actions are required to modify the allowable land uses in the Northside Project and in Continental City property, and how will compliance be assured?

The land use component of the Draft EIS/EIR and Condition LU-1 in Chapter V, Environmental Action Plan, presents a “Master Plan commitment” that:

“To the maximum extent feasible, all [Q] conditions . . . from the City of Los Angeles Ordinance No. 159,526 that address the Northside project area will be incorporated by LAWA into the Zoning Code Amendment and LAX Master Plan Implementing Ordinance for the Westchester Southside Project. Accepting that certain conditions may be updated, revised, or determined infeasible as a result of changes to the LAX Northside project, the final [Q] conditions for the Westchester Southside Project will ensure that the level of environmental protection afforded by the full set of LAX Northside projects [Q] conditions is maintained.” (Draft EIS/EIR, Chapter V, page 5-2).

Since this traffic reduction is critical to the projected Master Plan trip generation, the detail associated with this property needs to be firmly established. It is unacceptable to assume that certain conditions may be “updated, revised or determined infeasible” if they are necessary to bring about the decrease in collateral trips upon which the Master Plan projections are based. While there are some discussions of the Northside/Westchester Southside Project in the Draft EIS/EIR’s purpose and need chapter and Master Plan, Appendix Q, these are brief, general presentations lacking in specificity as to the actions needed to commit the City to limit these uses.

The importance of this lack of specificity in the definition of Project actions, as they relate to the Northside/Westchester Southside Project, is that there is no commitment by Los Angeles to insure that the traffic reduction represented by the changes in allowable land use will occur. The surface traffic capacity for the Project claimed through the reduction of traffic generation from the Westchester Southside Project is significant. Without a more adequate demonstration of the Master Plan's ability to achieve that reduction, and a concrete commitment to meeting those goals, the Draft EIS/EIR will remain inadequate.

D. The Transportation Planning Horizon Used in the Draft EIS/EIR is Improperly Shortened So As To Minimize the Full Build Out Surface Traffic Impacts of the Project.

The Draft EIS/EIR modeled future conditions for the years 2005 and 2015. The current regional transportation plan, however, uses 2025 as the horizon year. The use of a later year between 2015 and 2025 for analysis is proper in light of the fact that the Project is anticipated to take 16 years to complete.¹⁰ If the Project commences as early as 2002, it will not be completed until 2018, three years after the 2015 horizon has expired. With the year 2013 being the second greatest peak construction year (Draft EIS/EIR, page 4-270), the proposed Master Plan improvements will not be complete by the time the present horizon year of 2015 is reached. The import of the choice of 2015 as horizon year, before the Project is completed, is that the full build-out ("worst case") impacts of the Project will remain unanalyzed.

Further, while the impacts resulting from the adoption of the proposed Master Plan are generally evaluated against the Adjusted Environmental Baseline, much of the Draft EIS/EIR's discussion of surface traffic is compared to the No-Project/No-Action alternative (i.e., the alternative that assumes growth in operations and passenger demand at the Airport, along with completion of improvements already planned, but no off airport traffic or other development improvements). The comparison of the Project with two separate baselines in the years 2015 presents a misleading picture. While the reconstitution of the Northside Project may provide a reduction in the traffic generated in 2015, the existing airport improvements clearly permit growth beyond that currently possible. Therefore, the further into the future conditions are projected, the greater the effect of the proposed Master Plan improvements on traffic.

¹⁰ The Draft EIS/EIR, Purpose and Need Section (Chapter 2, pages 2-12 through 2-13) indicates that the Project will be implemented in two phases. The first phase will last six years and the following phase 10 more years.

E. The Impacts of Construction Traffic Are Largely Ignored.

While the Project's construction will stretch over a period of 14 years, the impacts of the numerous construction vehicles that will be in use during that period remain unexplored. First, the Draft EIS/EIR acknowledges a volume of construction vehicles which includes 2.8 trucks per minute, 10 hours per day, 6 days per week, or 1.2 trips per minute, 20 hours per day in a 7 day work schedule (Draft EIS/EIR, page 4-319). While the Draft EIS/EIR purports to address mitigation by recommending that trucks trips be divided among four locations on the construction site, that purported mitigation does not consider the trucks' impacts on surrounding arteries even a short distance from the construction site.

Moreover, the Project will admittedly coincide with the construction of Playa Vista, located approximately 2 miles north of the airport (Draft EIS/EIR, page 4-320). The Draft EIS/EIR contains little or no analysis of the cumulative impacts of the construction of these two projects on surface traffic on surrounding arteries and the San Diego Freeway. Moreover, the mitigation offered is slight. The Draft EIS/EIR offers to expand the ". . . Traffic Coordination Office . . ." to minimize the impacts of construction traffic (Draft EIS/EIR, page 4-320). This purported mitigation measure, even when combined with other assurances including that "construction traffic . . . can be managed . . ." (Draft EIS/EIR, page 4-320), and "traffic patterns around the airport for the general public would be largely maintained . . ." (*Id.*), does little, if anything, to assure that the manifest impacts of construction will be mitigated. The Draft EIS/EIR admits as much where it states "however, even with these commitments in place, the Project would still cause sufficient construction-related traffic to cause notable disruption of normal traffic flows near the airport." (*Id.*) Since construction is planned to last more than 14 years, the Draft EIS/EIR is basically stating that for that entire period, traffic is expected to be disrupted, and the Project's purported mitigation will be insufficient to restore stability.

Finally, the Draft EIS/EIR pays little or no attention to the traffic impact of vehicles used by construction workers. It states that construction employees will work in three shifts, and that the second shift will arrive before the first shift ends (Draft EIS/EIR, page 4-319). Using simple math, it appears that at some points during the day, parking would have to be provided for more than 8,000 workers when these two shifts overlap. While remote parking areas are suggested for construction employees, they are as far away as Palmdale, Van Nuys and Ontario (*Id.*). The likelihood of construction workers using such remote parking is slim to none. Therefore, the mitigation measure is largely useless. However, even if remote parking were utilized to any extent, the Draft EIS/EIR fails to discuss the traffic impacts of the shuttles which would bring the construction workers from these remote locations to the airport. In short, even though construction is expected to last for 14 years, the Draft EIS/EIR contains little, if any, analysis of the impacts of construction worker traffic which will take place on the entire street/freeway system 6 or 7 days a week during that period.

In summary, while "the general construction concept is to have many of the transportation improvements completed within the first five years after construction begins . . ." (Draft EIS/EIR,

page 4-318), the LAX Expressway and northeastern portion of the ring road from the San Diego Freeway to Sepulveda Boulevard would not be available to traffic until well after the first five years (Draft EIS/EIR, Table 4.3.2-18, page 4-318). Therefore, there would be no new routes available for mitigating the above impacts during the heaviest construction period.¹¹ As a consequence of the above omissions, the Draft EIS/EIR's analysis of construction traffic impacts is materially deficient.

F. The Draft EIS/EIR Lacks a Mitigation Monitoring Program.

The Draft EIS/EIR, Chapter V is entitled "Environmental Action Plan". It is not specific as to whether this constitutes a Mitigation Monitoring Program required by CEQA (CEQA Guidelines § 15091(d)). If it does represent a Draft Mitigation Monitoring Program, it is inadequate. The Section lacks a clear statement of the party responsible for implementing the mitigation, the mechanism for enforcement of the mitigation and the timing of implementation. Moreover, it lacks detailed explanation of the way in which the diminution of traffic from the Northside Project, as well as other surface traffic mitigation measures will be achieved.

III. THE DRAFT EIS/EIR NOISE ANALYSIS UNDERSTATES THE PROJECT'S AIRCRAFT NOISE IMPACTS.

A. The Draft EIS/EIR minimizes the Project's noise impacts by artificially inflating the Environmental Baseline.

As noted earlier, a threshold issue in environmental analysis is the establishment of a "baseline". The function of a "baseline" is to provide a benchmark of existing conditions against which the environmental impacts of a project may be measured. If the baseline is incorrectly designated at too high a level, the impacts of the Project will be improperly minimized. In this case, the Draft EIS/EIR utilizes three separate and distinct baselines for analyzing the impacts of the Project: (1) the Environmental Baseline (1996), i.e., the purported conditions in existence before implementation of the Project; (2) "No-Project" baseline for 2005 (and 2015) which includes "natural" growth on the airport resulting from implementation of already approved airport projects continued in the current Master Plan that purportedly would have occurred even if the Project is not implemented; and (3) Adjusted Environmental Baseline predicated on projected conditions in the years 2005 and 2015 with off-airport land use activities completed

¹¹ The Draft EIS/EIR states that Phase 1 of the Project would be 5-6 years long and end in 2005. As the Draft EIS/EIR cannot be approved before late 2001, at the earliest, and Phase 1 of the construction could not then begin before 2002, Phase 1 could not end until at least 2007 or 2008. Similarly, Phase 2 which is estimated to extend 10 years past the completion of Phase 1, would end in 2017 not 2015, as assumed in the Draft EIS/EIR. This is important because the impacts of construction, and associated traffic, will now be extending well past the period anticipated in the Draft EIS/EIR.

and regional circulation improvements in place, but without any improvement to airport facilities.

The Draft EIS/EIR chooses 1996 (i.e., the Environmental Baseline) as the base year for evaluation of aircraft noise impacts, and states that in 2015, the Project's horizon year, Alternative C "would reduce the total number of people exposed to aircraft noise above 65 CNEL compared to current conditions as represented by the Environmental Baseline year." (Draft EIS/EIR, page 4-11) **By using 1996 as the benchmark, the Draft EIS/EIR's noise analysis artificially minimizes the apparent growth in noise impacts associated with the Project. This is because, in 1996, many noisy Stage 2 aircraft remained in the fleet (which were then phased out in late 1999). When the Notice of Preparation was published in July 1997, the Project proponents knew with certainty at that time that some of the noisiest aircraft in its fleet would not operate after December 31, 1999, and that the removal of these aircraft from the fleet serving the Airport would reduce the size of the airport's noise exposure contours. The Draft EIS/EIR concedes that the "reduction in noise exposure is the result of a federally mandated phase out of older, noisier Stage 2 jets," and not the implementation of the Project. Despite that fact, the Draft EIS/EIR consciously skews the analysis by using 1996 as the Base Year for its noise analysis.**

The Draft EIS/EIR disregards the fleet mix changes brought about by the Stage 2 phase out. The Draft EIS/EIR's "Average Annual Day Operations and Fleet Mix - Environmental Baseline" (Draft EIS/EIR, Appendix D, page 11) includes a total of 139 noisy Stage 2 aircraft in the daily operations mix. In other words, nearly 7% of the aircraft included in the calculation of the baseline noise contour analysis are high noise producing aircraft the inclusion of which will increase the size of the baseline noise contours and, thereby minimize the apparent impacts of the Project.

Courts have displayed flexibility in dealing with cases involving complex long term environmental review. They have agreed that, for lengthy environmental review such as that at issue here, the analysis of such impacts as surface traffic (and aircraft operations) which normally fluctuate over time are properly assessed against a later baseline than the time of the publication of the Notice of Preparation. (Save our Peninsula Committee, *supra*, 87 Cal.App.4th at 125-126) Therefore, Project proponents are not tied to the 1996 baseline, the last full year of data before the year of Notice of Preparation Publication, but should, more properly, have used a year no earlier than 1999, the last full year of data available before publication of the Draft EIS/EIR. Moreover, that data should have been updated with available data from the year 2000. Absent such an update, the Draft EIS/EIR noise analysis is incomplete and, thus, inadequate.

B. The Draft EIS/EIR Fails to Satisfy Applicable Law Because it Improperly Analyzes the Health Effects of Aircraft Noise.

1. The Draft EIS/EIR Must Consider the Health Effects of Aircraft Noise.

The Draft EIS/EIR must fully consider all of the adverse health effects of aircraft noise. LAWA admits that its LAX Master Plan will create increased noise impacts upon the residents of the City of Inglewood. "Under Alternative C, which does not add a new runway, a decrease in noise exposure would occur in the City of El Segundo and the community of Del Aire with increases in portions of the community of Westchester and the City of Inglewood." Draft EIS/EIR Section 4.24.2 page 4-1040. There is strong scientific evidence of the adverse health effects of noise pollution on humans. Studies have shown clear health effects on animals, and these studies indicate the certainty of such effects on humans as well.

"A study sponsored by the EPA, constituting one of the most notable studies of animal noise exposure, examined cardiovascular effects of noise on monkeys. This research demonstrated that monkeys subjected to industrial noise at levels between 85 to 90 dba for several months developed significant elevations of systolic and diastolic blood pressure. It is particularly notable that these changes persisted long after exposure ceased, demonstrating that noise has a chronic effect on blood pressure."

Fred M. Svinth, Illingworth & Rodkin, Inc. "The Effects of LAX Aircraft Noise on Local Communities," January 2001, p. 9, attached hereto as Exhibit "I". LAWA admits that such studies exist and that noise has effects, but refused to seriously consider such reports. Instead, LAWA simply concludes that such studies are controversial and, therefore, that no in-depth analysis is required.

"Some studies suggest that there are indicators that high noise levels, particularly from aircraft, may have a detrimental effect on the cardiovascular system, mortality rates, birth defects, achievement scores, psychiatric admissions, sleep disturbance, and overall psychological well being; others show no conclusive evidence of these effects. However, the results of such studies continue to be controversial and are not accepted by the general scientific community at this time. Specifically, the scientific community has cited methodological and epidemiological problems with the studies and none of the studies has gained the universal acceptance from researchers that would allow them to be used as a basis for impact assessment."

Draft EIS/EIR Section 4.24.2 page 4-1041.

However, LAWA argues that it is impossible to "quantify" the relationship between noise and adverse human health effects. LAWA argues that no "threshold of significance" exists:

“Although there is consensus that noise has some health effects, there is no agreement as to the degree of the effects or the level at which they become significant. The scientific community and regulatory agencies have not developed numerical thresholds beyond which the health effects of noise are considered to be significant.”

Draft EIS/EIR Section 4.24.2 page 4-1046.

In other words, LAWA takes the position that the absence of a specific threshold absolves it from having to address this issue in any meaningful way in the Draft EIS/EIR. Instead, LAWA focused on overall noise exposure caused by its expansion plan. “Since it is not possible to quantify noise health impacts for a population, such as the people who live in the vicinity of an airport, this analysis focused by necessity on quantifying overall noise exposure.” Draft EIS/EIR Section 4.24.2 page 4-1039.

LAWA’s admitted inability to fully analyze the Health Effects of Aircraft Noise itself renders the planned expansion violative of existing law. LAWA improperly fails to consider the admitted potentially significant adverse health effects of noise. “Significant and unavoidable impacts associated with aircraft noise are expected to occur. Such noise exposure is considered to pose a potential significant and unavoidable impact relative to health effects of noise, to the extent there is such a relationship between the two.” Draft EIS/EIR Section 4.24.2 page 4-1050.

“The U.S. Environmental Protection Agency (USEPA) has taken the following position: ‘Research implicates noise as one of several factors producing stress-related health effects such as heart disease, high blood pressure and stroke, ulcers and other digestive disorders. The relationship between noise and these effects has not yet been quantified.’”

Draft EIS/EIR Technical Report 14b. Health Effects of Noise Technical Report. No Master Plan Commitments for the health effects of noise are proposed. Draft EIS/EIR Section 4.24.2 page 4-1046. LAWA must fully examine the health effects of aircraft noise in order to fulfill the requirements of NEPA and CEQA.

2. The Draft EIS/EIR NEEDS TO ADDRESS Aircraft Noise Interference with Classroom Activities and Sleep.

The Draft EIS/EIR fails to adequately address the interference of aircraft noise upon classroom activities and sleep. Interference with classroom activities and sleep are two of the most sensitive impacts of aircraft noise. LAWA admits the problem of interference with

classroom activities, but fails to analyze this problem to the degree required under CEQA. According to LAWA:

“Interference with classroom activities and learning from aircraft noise has been the subject of much recent research. Several studies have been performed, including studies at LAX, London’s Heathrow Airport, and Munich International Airport. These studies indicate that a relationship between aircraft-related noise and learning effects does exist, but that additional research is required to clarify how close the relationship is and at what noise levels the relationship appears. The relationship has been particularly difficult to document due to the confounding factors of background noise, school quality, and socioeconomic status. Additional research is being performed to try to account for these factors.”

Draft EIS/EIR Section 4.24.2 page 4-1043. Similarly, LAWA admits but dismisses summarily the very real problem of sleep disturbance caused by aircraft noise. LAWA states:

“Generally, laboratory studies have shown considerably more disturbance than field studies, perhaps due to the subject’s lack of familiarity with the location and experience. Sleep disturbance studies have also involved the collection of cumulative data from subjects.... A review of existing studies and literature indicates that additional research is required to clarify the relationships between aircraft-related noise and sleep disturbance.”

Draft EIS/EIR Section 4.24.2 page 4-1044.

LAWA tries to minimize the sleep disturbance caused by aircraft operations at LAX. LAWA states, “LAX undertakes a different operational procedure for takeoffs and landings between midnight and 6:30 a.m. These ‘over-ocean’ procedures route both arrivals and departures over Santa Monica Bay, directing aircraft noise away from residential areas to the east of LAX during nighttime hours.” Draft EIS/EIR Section 4.24.2 page 4-1045. However, due to constraints caused repeatedly by weather conditions, residents of Inglewood and other nearby communities are subjected to late night overflights. The Draft EIS/EIR fails to adequately analyze these issues.

IV. THE DRAFT EIS/EIR AIR QUALITY ANALYSIS IS INADEQUATE.

The Draft EIS/EIR's air quality analysis exhibits serious deficiencies, not the least of which is the total absence of a formal air quality conformity analysis required under federal law where, as here, the Project's air quality impacts are not claimed to be insignificant (see 42 U.S.C. § 7506¹²). The absence of a conformity analysis necessarily renders the following comments preliminary.

A. The Baseline for the Draft EIS/EIR Air Quality Analysis is Not Appropriately Estimated.

¹² “No department, agency, or instrumentality of the federal government shall engage in, support in any way or provide financial assistance for, license, permit or approve any activity which does not conform to an implementation plan . . .” (42 U.S.C. § 7506(c)(1))

The Draft EIS/EIR assumes that annual aircraft operations will be essentially identical regardless of whether the Preferred Alternative is implemented (Draft EIS/EIR, page ES-9). Under the No-Action/No-Project Alternative, total operations are expected to be 98 percent of operations under the preferred expanded capacity scenario (Alternative C). Furthermore, air passenger operations activity will actually be *higher* under the No-Action/No-Project Alternative. At the same time, the Preferred Alternative moves about 15 percent more passengers through higher aircraft load factors. Basic economic theory, however, dictates that under free market conditions, demand will reach equilibrium for a given level of supply at a certain market cost (including time costs associated with delays, congestion, etc.). If the supply curve (for air transportation) is then shifted, as would occur under an increased capacity situation such as that proposed,¹³ the supply/demand equilibrium for the same level of market cost will shift to a point of higher demand. This shift is often referred to as induced demand, and analyses which do not consider this effect (or which assume demand levels counter to market behavior as appears to be the case with the Draft EIS/EIR) are not accurate in general, or specifically with respect to future air quality conditions under any of the various alternatives. Viewed from a practical rather than theoretical perspective, the Draft EIS/EIR presumes that the Airport will support over 391,000 aircraft landing and takeoff (LTO) cycles in 2015 by doing nothing other than carrying through with those projects already adopted. Although operations without the Project would be constrained by greater delays as well as excessive times to reach the airport, the Draft EIS/EIR does not account for the discouraging effects of these delays, and assumes that under the Preferred Alternative, specifically designed to relieve these problems of congestion and delay, the total number of annual LTOs will increase by less than 2 percent (to 398,000) over the No-Action/No-Project Alternative. There are only two possible explanations for this relationship: (1) either usage under the No-Action/No-Project baseline is overstated; or (2) usage under the Preferred Alternative is understated. Correspondingly, either emissions for the No-Action/No-Project baseline are overstated or emissions for the Preferred Alternative are understated. The result is an artificial (and erroneous) minimization of the difference in emissions between baseline conditions and those of the Project.

This same issue affects stationary source emissions. Increased airport capacity can be expected to attract associated industrial and commercial activity into the area. This attraction would not occur without the increased capacity and, therefore, must be accounted for if a true assessment of airport emission impacts is to be determined. Note that this commercial development is distinct from currently planned commercial development, in that it occurs due to airport capacity expansion, but outside the formal planning process of the airport. One must recognize that the estimates of reduced emissions under the action alternatives (either the preferred or alternative scenarios relative to a No-Action/No-Project scenario) are due almost entirely to “flow” improvements in the form of reduced taxiway congestion and improved traffic

¹³ The Preferred Alternative lengthens and reconfigures runways, adds a new West Terminal, and improves traffic flow.

movement both on and offsite. If these congestion reductions are eliminated or reduced through increased air travel or associated demand that is not properly accounted for in the Draft EIS/EIR, the predicted emissions impacts will not be accurate.

B. Future Background Pollutant Concentrations Are Not Appropriately Estimated.

Background pollutant concentrations are required to accurately estimate the impact of the proposed Airport expansion on National Ambient Air Quality Standards/California Ambient Air Quality Standards (“NAAQS/CAAQS”) compliance. These concentrations must account for the combined impacts of the universe of emission sources not explicitly accounted for in the airport analysis. In effect, the background concentrations determine the emissions baseline upon which Airport emissions are placed. If this base is underestimated, the overall affect of airport expansion on NAAQS/CAAQS compliance could be similarly understated. Alternatively, if the base is too high, the Draft EIS/EIR analysis could be conservative. While the Draft EIS/EIR presumes the latter (Draft EIS/EIR, Technical Appendix G, page 46), it contains no data to support such a conclusion and some reason to believe that the converse may be true.

Current short term (sub-annual) background concentrations for the Draft EIS/EIR are based on measurements taken at an onsite monitoring station located just east of the southern runway configuration. Current annual concentrations are based on data collected at a South Coast Air Quality Management District (“SCAQMD”) monitoring facility (Hawthorne) located near, but southeast of the Airport (Draft EIS/EIR, Technical Report 4, Attachment A, page 3). On the premise that measurements from these sites inherently include emissions from the Airport, the Draft EIS/EIR concludes that such emissions represent conservative background concentration baselines for air quality analysis (since Airport emissions will be added on top of a background that already includes Airport emissions).

However, the prevailing wind direction for the Airport area is southwest to northeast (Draft EIS/EIR, Technical Report 4, Attachment A, page 3). Therefore, there is probably little influence from the Airport on the offsite concentrations used as background, as well as only moderate influence on the onsite-based background concentrations. The bulk of airport activity, including all terminal and motor vehicle operations occur under the influence of a prevailing wind plume that crosses Airport property to the north of the onsite monitoring station. While certain aircraft takeoff and queuing emissions are undoubtedly accounted for in the onsite baseline concentrations, these represent only a small fraction of overall airport emissions. Comparative data for concentrations from both monitoring stations could demonstrate the validity of the claim of conservatism, (i.e., do the observed concentrations for identical monitoring periods show a higher background at the onsite station?), but the Draft EIS/EIR apparently contains no data for the offsite monitoring station (other than the specific background concentrations used in the Draft EIS/EIR and associated documents, which are not comparable to the data for the onsite monitoring station).

More importantly, the emissions inventory rollback techniques used to forecast future background concentrations (Draft EIS/EIR, Technical Appendix G, pages 45-46) are of questionable validity for the Airport area. Background concentrations as well as future emission reduction influences around the Airport are constrained by geography. Since the prevailing wind flows from the southwest to the northeast, the Pacific Ocean represents a physical constraint that may significantly influence emission reduction impacts on background concentrations. In effect, the implemented rollback procedure to estimate future background concentrations reduces current background concentrations in proportion to expected *regional* emission inventory reductions over the same time period. Therefore, this procedure inherently assumes that inventory reductions are homogeneous throughout the region in terms of their influence on background concentrations. This is perhaps a viable assumption in instances where one part of a region has similar source characteristics with another, but the Airport region is clearly constrained to those source characteristics along the Pacific coastline to the immediate south of the Airport. It is the expected reductions from these sources in particular that should be used to adjust Airport background concentrations.

Generally background concentrations for 2005 are reduced 30 to 40 percent while concentrations for 2015 are reduced 50 to 60 percent from the current measured data (Draft EIS/EIR, Technical Report 4, Attachment A, page 4). Clearly this assumes significant emission reductions will affect coastal monitoring sites and provides substantial headroom for emissions increases within the confines of the NAAQS/CAAQS. These reductions probably represent the most significant influence on forecast pollutant concentrations in 2005 and 2015. It is critical that the propriety of the assumed background concentrations at least be supported by comparative analysis of current Airport and offsite monitoring data as well as analysis of emissions source classifications for the area immediately to the south of the Airport with the remainder of the air basin. This comparison will either provide the proper support for the currently implemented approach or suggest a more appropriate alternative.

C. Reverse Thrust Emissions from Aircraft Are Not Included in the Draft EIS/EIR Air Quality Analysis.

The Draft EIS/EIR makes an affirmative determination not to address emissions from aircraft reverse thrust operations, ostensibly on the basis of inadequate emission factors and short usage times (Draft EIS/EIR, Technical Appendix G, page 4). Both of these claims are misleading. First, reverse thrust is essentially a high thrust operating mode and emission factors for such modes (i.e., climbout and takeoff) are readily available. Common practice is to use takeoff emission factors. Second, it is true that the time in mode for reverse thrust operations is short, however high thrust modes produce very high unit time NO_x. For example, at a commonly utilized reverse thrust mode time of 15 seconds, increased NO_x emissions would be equivalent to the NO_x produced by increasing overall takeoff time by 35 percent (0.7 minutes plus 0.25 minutes versus 0.7 minutes). Since takeoff accounts for about 35 percent of total aircraft NO_x (Draft EIS/EIR, Technical Report 4, Attachment C), the overall aircraft NO_x inventory could increase by nearly 13 percent simply due to the inclusion of reverse thrust-related emissions

alone. Without some affirmative determination that such operations will be prohibited under the action alternatives, reverse thrust emissions should be included in the Draft EIS/EIR air quality analysis.

D. The Applicability of the Construction Equipment NO_x Standard is Overstated.

The Draft EIS/EIR states that only construction vehicles meeting a 2.5 grams per brake horsepower-hour (g/bhp-hr) NO_x standard will be used for airport construction projects by 2005 (Draft EIS/EIR, Technical Appendix G, page 3). Furthermore, this requirement will be phased in between 2001 and 2005, beginning at 20 percent of vehicles and increasing at a rate of 20 percent per year. This "requirement" raises several concerns as it is applied to the construction equipment emissions analysis in the Draft EIS/EIR.

First, the 3.0 g/bhp-hr NMHC+NO_x standard (that is the basis for the 2.5 g/bhp-hr NO_x assumption) for construction vehicles does not take effect until 2005 for 300-750 horsepower (hp) engines, 2006 and 2007 for 100-300 hp engines, or not at all for engines of other hp. Mandating this equipment for Airport work at an accelerated schedule beginning in 2001 may or may not be successful, but clearly requires some statement of commitment by the regulated parties. Voluntary, so-called "Blue Sky Series," engines can be certified by manufacturers before 2005 but there is no requirement to do so (and little incentive since these engines cannot be used in the emissions averaging programs associated with non-Blue Sky engines, averaging programs which are currently relied on by all heavy duty engine manufacturers for emissions standards compliance). In reality, construction firms will only be able to provide equipment that is available on the market and it is dubious that the number of engines meeting the suggested standard in the required years will be significant.

Second, the mandatory "clean engine" standards that do begin in 2001 require NO_x at levels around 4.0 g/bhp-hr (an exact value is not possible since the standard is again expressed as NMHC+NO_x, in this case 4.8 g/bhp-hr). However, these standards also only apply to 300-750 hp equipment. While a number of construction equipment engines fall into this category, many others range from as low as 25 hp up through 300 hp. For these lower hp categories, standards do not begin until 2003 or 2004 and get progressively less stringent as engine size decreases (to 5.6 g/bhp-hr for engines below 100 hp).

Third, even if this low emissions requirement could be enforced (i.e., allow use of only new Blue Sky Series engines at the Airport), an assumption of 100 percent in-use compliance is overly optimistic. While it is not possible to say with certainty what fraction of equipment may operate at emissions levels above certification standards, experience has demonstrated that engines employing sophisticated engine management strategies and aftertreatment controls (as is expected for engines meeting these stringent standards) are subject to both malperformances and malmaintenance effects. For first generation engines, such problems are usually exacerbated. What can be stated with certainty is that construction emissions impacts will be larger than the level acknowledged in the Draft EIS/EIR.

E. General Emission Factors for Offroad Equipment are Understated.

In general, it appears that the emission factors employed for offroad engines, even in the absence of the 2.5 g/bhp-hr issue noted above, are significantly underestimated. This underestimation affects not just construction equipment, but both baseline and ongoing aircraft Ground Support Equipment (“GSE”) operations, and results from the fact that outdated emission factor sources were utilized. The net effect is that airport emission and air quality impacts are underestimated.

Offroad engine emissions knowledge is currently in a state of rapid development and estimation techniques need to maintain currency with the latest methods. In California, this would imply use of the California Air Resources Board’s (“CARB”) OFFROAD emission factor model, while nationally a similar model termed NONROAD has been developed by the U.S. Environmental Protection Agency (“EPA”). While development continues on both, they clearly represent the most up-to-date compendiums of current offroad engine emissions estimation techniques. For example, these models employ the most recent emission factor test data, emissions deterioration test data, and equipment size and activity factors. References cited in the Draft EIS/EIR (Draft EIS/EIR, Technical Report 4, Attachment A), such as the EPA’s AP-42 and Procedures for Emissions Inventory Preparation documents as well as the SCAQMD’s CEQA Handbook, employ less developed and, in many cases, seriously outdated data.

An example of the magnitude of the emissions underestimation can be derived by comparing emission factors across the alternative methods. The Draft EIS/EIR relies on the use of the FAA’s Emissions Dispersion and Modeling System (“EDMS”) to generate GSE emission estimates. However, EDMS includes significantly outdated GSE emissions data.¹⁴ A quick comparison indicates that CARB OFFROAD model and EPA NONROAD model GSE (average) emission rates (for the same equipment activity distribution assumed in the EIS/EIR) are, for diesel equipment, from 7 to 13 times greater for VOC, 5 to 10 times greater for PM, 5 to 9 times greater for CO, 4 to 5 times greater for NO_x, and 4 to 5 times greater for SO₂. For gasoline GSE, the models produce average emission rates 10 to 20 times greater for VOC, 1 to 6 times greater for PM, 15 to 16 times greater for CO, 6 to 9 times greater for NO_x, and 2 to 4 times greater for SO₂. The impact of using outdated emission rates is clearly significant and should be reevaluated if realistic air quality impacts are to be derived.

¹⁴ This situation may be improved in the latest version of EMDS, which was released subsequent to the completion of the Draft EIS/EIR.

F. Ground Support Equipment Populations Are Not Appropriately Specified.

As stated above, the Draft EIS/EIR uses the FAA's EDMS model to estimate GSE emissions (Draft EIS/EIR, Technical Report 4, Attachment A). Inherent within this approach is an assumption that EDMS properly estimates GSE populations. Since the current GSE population at the Airport is known, it would be appropriate to determine whether EDMS assumptions are consistent with the Airport's actual population and use-hour statistics. This would provide support for the validity of EDMS equipment estimation algorithms and allow for a more appropriate assessment of the accuracy of the GSE emissions estimates and air quality impacts of the Draft EIS/EIR.

G. Emissions Benefits of Conversion of GSE to Electric, Hybrid, and Alternative Fuels are Overstated.

The Draft EIS/EIR contemplates a widespread GSE replacement program under all three of the action alternatives, while retaining primarily fossil fuel powered GSE for the No-Action/No-Project Alternative (Draft EIS/EIR, Technical Report 4, Attachment L). While this could be construed as a mitigation measure and, in fact, is listed as the single most effective mitigation measure on the list of potential mitigation measures included in the Draft EIS/EIR (pages 4-514 through 4-519), it is arbitrary to apply the measure only to the action alternatives, as there are no specific constraints to such substitution today or under the No-Action/No-Project Alternative. Electric GSE is cost effective from a market standpoint today. Therefore, whatever incentive or mandate will be offered under the action alternatives to move toward electrification could just as readily apply today. Required infrastructure modifications are relatively modest, with no dependency on the expansions associated with any of the action alternatives. But by far the most troubling issue is that the replacement program already appears to be accounted for in the "unmitigated" emission estimates for all three action scenarios. If this is the case, no additional emission reductions will be achieved through GSE electrification as is claimed in the proposed list of mitigation measures.

H. Incorrect Aircraft PM Emission Factors Are Used in the Draft EIS/EIR Air Quality Analysis.

Two issues exist with respect to the aircraft PM analysis that result in an underestimation of the Project's potential air quality impacts. First, it appears that the Draft EIS/EIR is based on the incorrect emission factors from the supporting analysis undertaken to develop those factors (Draft EIS/EIR, Technical Report 4, Attachment H). Second, it appears that the approach used to

develop PM emission factors for aircraft¹⁵ produces estimates that are not consistent with previous PM emission testing results.¹⁶

Analysis of PM emission factor estimation reveals that the basic estimation approach used in the Draft EIS/EIR yields an emission factor that only considers the basic non-volatile portion of particulate. An adjustment factor (that varies with fuel sulfur content) exists and should be used to correct the estimate to total PM (Draft EIS/EIR, Technical Report 4, Attachment H). This factor is calculated to be about 2.6 for low sulfur (about 70 ppmW) jet fuel and 14.7 for high sulfur (about 675 ppmW) jet fuel.¹⁷ Since existing EPA data demonstrates that U.S. jet fuel averages about 600 ppmW sulfur, the appropriate adjustment factor for the Draft EIS/EIR would be about 13.2. However, from figures presented in the Draft EIS/EIR, it appears that the unadjusted emission factors were used for all emissions analysis. If so, PM emission impacts are significantly underestimated and should be reassessed after applying an adjustment to increase the PM emission rate by a factor of 13.

In addition there is a potential deficiency in the approach employed to estimate PM emission factor data. The underlying need for a statistical estimation technique such as that employed cannot be disputed as the available aircraft PM emissions testing database is both small and dated. However, the Draft EIS/EIR (Technical Report 4, Attachment H) statement that the age of that data renders it valueless are questionable. Engine technology has advanced relative to the engines represented in the test database, but the fundamental physical and chemical combustion characteristics that give rise to PM formation have not. The additional claim that the existing aircraft emission factors are not of value since they reflect total PM as opposed to PM-10 is also without merit. Virtually 100 percent of combustion-related PM is PM-10, so any error resulting from the substitution of total PM for PM-10 will be insignificant.

¹⁵ The International Civil Aviation Organization (“ICAO”) emissions certification process for aircraft does not include PM, so alternative emission factor estimation approaches are required.

¹⁶ Adjustments not employed in the Draft EIS/EIR may compensate for most of this deficiency.

¹⁷ This calculation is based on data presented in the Draft EIS/EIR (Technical Report 4, Attachment H).

In fact, the PM emission factor estimation approach employed in the Draft EIS/EIR requires just such an assumption of equivalency between total PM and PM-10 (as stated in Technical Report 4, Attachment H).

If relationships between aircraft PM and another routinely measured pollutant can be developed for one or more of the standard aircraft operating modes, then measured values for this “independent” pollutant can be used to estimate PM emission rates in that mode (or modes). Such a statistical approach can take advantage of the limited existing PM emissions database, while at the same time recognizing the substantial progress that has been made in aircraft engine performance. It is, however, critical that such relationships consider possible operating mode-specific differences in any identified PM relationship, as engine and combustion efficiency vary substantially across modes. For example, one would expect PM emission rates to be inherently low in high efficiency (high NO_x) modes of operation since the same high temperature, high pressure conditions that give rise to high NO_x also favor more complete fuel combustion. Conversely, PM would be expected to be high in low efficiency combustion modes. In short, it should not be expected that the significance of any inter-species relationship(s) is/are invariant across the full range of operating modes.

A very strong statistical relationship between measured PM and the inverse of measured NO_x is observed in three of the four standard aircraft operating modes (approach, takeoff, and climbout), with coefficient t-statistics all significant at 99-plus percent confidence. A strong coefficient can also be observed for the taxi mode, but it explains virtually none of the observed variation in PM and NO_x (whereas variance explanatory significance exceeds 99 percent confidence for the other three modes). The magnitude of the relationship coefficients varies from 28.4 in takeoff mode to 45.0 in climbout mode, and is 33.0 in approach mode. While all three modes exhibit significant relationships, takeoff mode serves as the best basis for an overall relationship, as it statistically produces the smallest root mean square error based on regression data (an error 35 to 40 percent lower than those of climbout and approach modes). Using this takeoff mode PM-to-NO_x relation as a means to estimate aircraft takeoff PM emission rates for each of the engines with NO_x measurements in the overall ICAO emissions database, PM emission rates for the other three operating modes (climbout, approach, and taxi) can be developed based on observed statistical relationships between mode-specific PM and takeoff PM (i.e., PM-to-PM regressions across modes). Linear coefficients for all three modes (1.42 for climbout, 1.53 for approach, and 3.10 for taxi, all in pounds per thousand pounds fuel burned space) are significant at 99-plus percent confidence, with adjusted correlation coefficients for climbout and approach at 0.78 and 0.83 respectively. Taxi mode correlation is poor, but the PM-to-PM relation does account for observed variance at greater than 99 percent confidence.

Using existing ICAO emissions measurement statistics, this alternative approach produces PM emission rates that are 4 to 37 times higher than those used in the Draft EIS/EIR. The smallest differentials are observed at the highest thrust modes. The differentials grow with reducing thrust possibly because the Draft EIS/EIR approach does not take operating efficiency differentials between modes into consideration. Nevertheless, for a typical LTO cycle (as per

Draft EIS/EIR times-in-mode), the aggregate aircraft PM emission factor will be underpredicted by a factor of 17 using the Draft EIS/EIR approach. The effect on PM air quality analyses is obvious.¹⁸

I. Aircraft SO₂ Emissions are Underpredicted.

The Draft EIS/EIR relies on version 3.2 of the EDMS model to predict aircraft SO₂ emissions (Draft EIS/EIR, Technical Appendix G, page 4). This model underestimates aircraft SO₂ emissions by a factor of two due to reliance on an incorrect AP-42 emission factor (the emission factor was developed without accounting for the factor of two ratio between SO₂ mass and fuel sulfur mass). To the extent that the Draft EIS/EIR already demonstrates potential ambient SO₂ concerns, those concerns will be exacerbated by this underprediction.

J. The Assumption of Gate-Based Power and Air for All Aircraft is Questionable.

The Draft EIS/EIR assumes that 100 percent of air carrier gate power and conditioned air needs will be satisfied by gate-based electrically powered systems as opposed to fossil fuel powered auxiliary power units (APU) or GSE (Draft EIS/EIR, Technical Appendix G, page 10). Experience has shown that even under conditions where gate-based equipment is available, not all airlines or aircraft will utilize it consistently. This seems to be especially true for quick-turnaround airlines such as Southwest. Although the assumption of 100 percent availability and usage affects the no action and action scenarios equally, it is important from an ambient air quality perspective to account for the full range of expected emissions. Without some definitive airport policy that gate-based systems (both power and air) be used and that any on-board APU be shut down until needed for main engine startup, the Draft EIS/EIR would present a more realistic assessment of aircraft emissions if it adjusted the percentage of gate-based system usage to match currently observed use rates at the Airport.

K. APU Emission Factors for SO₂ and PM Not Considered.

¹⁸ Interestingly, if the appropriate carbon-to-total PM emission factor correction of 13.2 is implemented as suggested in the support material for the Draft EIS/EIR (Technical Report 4, Attachment H), the bulk of the emission factor differentials between the two estimation approaches virtually disappear (i.e., a correction factor of 13 versus an underestimation factor of 17 for an aggregate LTO). Nevertheless, significant differences would still exist on a mode specific basis.

APU emission factors for both SO₂ and PM are assumed to be zero. This results from deficiencies in the EDMS model and should be corrected to properly estimate aircraft-related air quality impacts. SO₂ emissions are a function of fuel sulfur content, so that emission rates can be readily calculated and applied. APU PM emission rates can be developed using the same methodology applied to main aircraft engines. The potential impacts of this deficiency would be magnified were the Draft EIS/EIR to properly attribute some fraction of gate power and air support to APU.

L. Aircraft Taxi Times are Not Included in the Draft EIS/EIR or Supporting Data.

Aircraft taxi-idle times are not included in the Draft EIS/EIR, its technical appendices or supporting documentation.¹⁹ It can be deduced from the included emissions estimates for aircraft taxiing that those emissions decrease substantially under the action scenarios, but the actual times should be included to allow the public an opportunity to better evaluate their propriety. In addition, the ability of SIMMOD to accurately estimate aircraft taxi times must be demonstrated by comparing SIMMOD predictions for current conditions at the Airport to observed taxi times at the Airport. The issue of aircraft taxi times is critical. The bulk of Aircraft VOC and CO emissions are generated during taxiing. In addition, although NO_x emission rates are low during taxiing, the amount of time spent in taxi mode results in a significant taxi contribution to overall NO_x emissions. Most critically, it is expected that virtually all of the aircraft emissions differential between the project baseline and the project alternatives is due to assumed reductions in aircraft idle time. Clearly, it is important that taxi times be accurately modeled. However, sufficient information is not included in the Draft EIS/EIR to determine that accurate modeling was performed.

¹⁹ The Draft EIS/EIR contains references to the development of the taxi/idle times using SIMMOD, but no actual indications of what those times were.

M. The Project's Conformity Cannot Be Determined from Data and Analysis Contained in the Draft EIS/EIR.

Even without consideration of the various issues noted above, the Draft EIS/EIR presents several air quality concerns relative to the NAAQS/CAAQS under the Preferred Alternative. Although a series of mitigation measures are discussed and preliminary emission reduction estimates presented, these estimates are not documented and therefore, the calculation methodologies cannot be evaluated. The Draft EIS/EIR defers formal review of potential mitigation measures until a Final EIS/EIR is developed (Draft EIS/EIR, page 4-459). Similarly, the Draft EIS/EIR acknowledges the applicability of federal conformity requirements, but defers both the conformity analysis and a proposed conformity determination to the Final EIS/EIR (Draft EIS/EIR, page 4-460). Unfortunately, such an approach makes it impossible to comment constructively on either potential emission mitigation measures or the conformity process, since these processes will be released for comment only after the underlying decision-making has been finalized.

N. The Draft EIS/EIR Fails to Satisfy Applicable Law Because it Does Not Adequately Address the Impact of Toxic Air Pollutants.

1. The Draft EIS/EIR Lacks A Proper Baseline Regarding Air Toxics.

The Draft EIS/EIR does not contain a proper baseline for air toxics emissions from LAX and LAX-related sources. As a result, it does not adequately address the effects of toxic air pollutants upon human health, including the health of the residents of the City of Inglewood.

CEQA requires that an EIR includes a description of the environment in and around the project at the time of the Notice of Preparation. CEQA Guidelines §15125(a). Such a description, or baseline, serves as the basis for the EIR's analysis of the environmental impacts of a project. CEQA also requires that detailed analysis of the potential environmental impacts from each of the projects contained in the aviation alternatives cannot be deferred to subsequent environmental documents. Public Resources Code § 21100; Stanislaus Natural Heritage Project v. County of Stanislaus (1996) 48 Cal.App.4th 182. The Draft EIS/EIR does not contain an adequate basis from which to determine the current impact on human health of air toxics emitted by LAX. "The HHRA did not evaluate impacts of toxic air pollutants associated with current airport operations." Calkins Phase I Report, p. 8. As noted by Mr. Calkins, this oversight means that LAWA does not provide a sufficient baseline from which to draw later conclusions. Without a baseline, LAWA cannot adequately assess the environmental effects of its plans to expand LAX.

2. LAWA Failed To Properly Study Toxic Air Emissions.

The Draft EIS/EIR does not properly study toxic air emissions related to LAX. LAWA's Health Risk and AirToxics evaluation is deficient due to the failure to organize and complete a study, such as the Air Quality and Source Apportionment Study, prior to the release of the Draft

EIR/EIS. The Air Quality and Source Apportionment Study are not yet complete. This study will shed important information on the health impacts to the surrounding community as well as identify mitigation measures. It will also determine the contribution of various airport-related activities on selected air pollutant concentrations in relation to those pollutants caused by other, non-airport sources in the surrounding community without the Source Apportionment study. LAWA cannot assess the incremental impact of LAX operations on local air quality. Therefore, LAWA has failed to investigate this area fully before preparing the Draft EIS/EIR. A prudent course of action would be to place any LAX expansion plans on hold until completion of this study. This would allow proper consideration of the serious human health issues addressed in this study. Without this study, the Draft EIS/EIR will not withstand scrutiny under CEQA and NEPA.

3. LAWA's Health Risk Assessment Does Not Adequately Factor Time as a Variable.

The Health Risk Assessment in the Draft EIS/EIR should be extended to consider a longer time period. There do not appear to be any tables or data in the Draft EIS/EIR on cancer and non-cancer health risks for any year after 2015. However, the operation of the expanded airport during those latter years may well have continuing impacts on the residents of the surrounding communities. Health impacts are often seen in the resident population over a much longer time span than the 15-20 years assessed in the Draft EIS/EIR tables. Other major planning assessments, such as the RTP (2025) and the AQMP (2030), examine impacts of their action over a much longer time frame. Calkins Phase II Report p. 22. The Health Risk Assessment in the Draft EIS/EIR should be extended to conform to this model.

4. LAWA's Study Of Air Pollutants Fails to Consider Relevant Issues.

It is unclear in the Draft EIS/EIR what LAWA's criteria are for determining net change in chronic and acute hazard indices for air pollutants. LAWA does not include the criteria pollutants in this analysis, and this is a critical, indeed fatal, omission. The results of the Source Apportionment study, which was only recently initiated, would have provided valuable input to assessing criteria (NAAQS) as well as various toxic air pollutant impacts on health, if it were available to the LAWA at the time of preparation of the Draft EIS/EIR. The Draft EIS/EIR also appears to ignore the incremental cancer and non-cancer risks to people who do not "receive a certain hazard level criterion." Calkins Phase II Report p. 22. These issues must be addressed and resolved in the Draft EIS/EIR.

V. THE DRAFT EIS/EIR DOES NOT MEET THE REQUIREMENTS FOR ALTERNATIVES ANALYSIS OF EITHER CEQA OR NEPA.

A. The Draft EIS/EIR Alternatives Analysis Does Not Conform to the Requirements of CEQA.

The LAX Master Plan and Draft EIS/EIR fail to conform to CEQA because they do not properly consider alternatives to expansion at LAX. Proposals that entail expansion at other airports instead of LAX should have been analyzed and considered. Instead of considering only three “build” alternatives, each of which called for massive expansion of LAX (in comparison to a flawed No Action/No Project Alternative), LAWA and the FAA should have considered alternatives that included expansion and/or construction at Ontario Airport, El Toro Marine Corps Air Station, Palmdale Airport and March Air Force Base.

In discussing alternative locations for a project, the CEQA Guidelines state, “The key question and first step in analysis is whether any of the significant effects on the project would be avoided or substantially lessened by putting the project in another location.” CEQA Guidelines § 15126.6(f)(2). The CEQA Guidelines further state:

“An EIR shall describe a range of reasonable alternatives to the project, or to the location of the project, which would feasibly attain most of the basic objectives of the project but would avoid or substantially lessen any of the significant effects of the project, and evaluate the comparative merits of the alternatives. The range of alternatives required in an EIR is governed by a ‘rule of reason’ that requires the EIR to set forth only those alternatives necessary to permit a reasoned choice. The alternatives shall be limited to ones that would avoid or substantially lessen any of the significant effects of the project.”

CEQA Guidelines §§ 15126.6(a), (f).

According to LAWA, its “preferred” alternative, Alternative “C”, causes fewer substantial impacts to the environment surrounding LAX than its other alternatives, “A” and “B.” However, the impacts that it does cause are substantial. Moreover, the analysis does not consider whether any of the significant effects of the project would be avoided or substantially lessened by putting the project in another location, as required by CEQA Guidelines, Section 15126.6(f)(2) cited above. The CEQA Guidelines state that alternatives that cause less environmental harm must be considered. Accordingly, inasmuch as the Draft EIS/EIR fails to consider another location, i.e., Ontario, Palmdale, El Toro, etc., the Draft EIS/EIR fails to follow the CEQA Guidelines.

Feasible alternatives to massive expansion of LAX do exist. The Guidelines set forth a number of factors to consider when determining whether or not an alternative is feasible.

“Among the factors that may be taken into account when addressing the feasibility of alternatives are site suitability, economic viability, availability of infrastructure, general plan consistency, other plans or regulatory limitations, jurisdictional

boundaries (projects with a regionally significant impact should consider the regional context), and whether the proponent can reasonably acquire, control or otherwise have access to the alternative site (or the site is already owned by the proponent).”

CEQA Guidelines section 15126.6.

Considering these feasibility factors in connection with expansion at LAX illustrates why the LAX Master Plan and the Draft EIS/EIR are not consistent with CEQA. LAX is located in the midst of a heavily populated residential area. The area is not well suited for the airport operations that currently exist, let alone massive expansion. LAX is economically viable, but expansion of LAX offers little, if any, additional economic benefit regionally when compared to other expansion scenarios considered by the planning body for Southern California, the Southern California Association of Governments (“SCAG”). “Southern California Aviation Industry Impact Analysis,” CIC Research, Inc., July 11, 2000, p. v, attached hereto as Exhibit “C”. The LAX Master Plan contemplates massive construction at LAX because, as it stands today, the infrastructure at LAX is not sufficient to handle the expanded operations in the plan. In reality, however, this places LAX in a similar position to that of every other airport in the area. If LAX is to expand, massive construction will have to take place. The LAX Master Plan is simply not consistent with other plans, in particular SCAG’s 2001 Regional Transportation Plan (“RTP”) (see below for further discussion) and the 1999 and 2001 Air Quality Maintenance Plan’s (“AQMP’s”). Lastly, the LAX Master Plan virtually ignores the regional approach to airport expansion, by failing to fully analyze any alternative that does not call for massive expansion at LAX. Given the fact that LAWA owns several of the other airports in the region meets or exceeds the feasibility of expansion of LAX, when considering the factors mandated by CEQA.

B. The Draft EIS/EIR’s Alternatives Fail to Satisfy the “Purpose and Need” for the Project.

The mandate to evaluate and compare alternatives is the “heart” of an EIS (CEQ Guidelines, § 1502.14). FAA Order 1050.1D, paragraph 63, implementing NEPA, mandates that an EIS “shall briefly specify the underlying purpose and need to which the agency is responding in proposing the alternatives including the proposed action.” The FAA Order further requires that the EIS Alternatives analysis include a rigorous exploration and objective evaluation of all reasonable alternatives. Courts have concluded that to be reasonable, the suggested alternatives must meet the goals of the proposed action.²⁰

The Draft EIS/EIR’s alternatives analysis fails to meet the stated goals of the Project. The Draft EIS/EIR states that the general “[p]urpose and objectives of the Master Plan are to

²⁰ See, generally, City of Carmel-By-The-Sea v. United States DOT, 123 F.3d 1142 (1997); National Wildlife Federation v. Federal Energy Regulatory Commission, 912 F.2d 1471 (1990).

provide... sufficient airport capacity for passengers and freight in the Los Angeles region to sustain and advance the economic growth and vitality of the Los Angeles region.” (Draft EIS/EIR, volume 1, pg. 2-1) More specifically, the Draft EIS/EIR outlines three objectives which the Project needs to satisfy: (1) “to respond to the local and regional demand for air transportation during the period 2000 to 2015, taking into consideration the amount, type, location, and timing of such demand”; (2) “to ensure that new investments in airport capacity are efficient and cost-effective, maximizing the return on existing infrastructure capital”; and (3) “to sustain and advance the international trade component of the regional economy and the international commercial gateway role of Los Angeles.”²¹

²¹

Id.

It is not clear, however, that the proposed runway improvements that form an integral part of Alternative C, the Preferred Alternative, constitute a superior, or even an efficient way to accomplish the Project's stated purposes. For example, all three of the Project's objectives could potentially be, at least partially, achieved through airspace/air traffic modifications, both within the terminal airspace and in the en route system. This alternative is neither acknowledged nor explored in the Draft EIS/EIR. Nevertheless, this conclusion is supported by the fact that the Dual Civet arrival configuration has reduced arrival delay for operations from the east significantly since 1998 and has resulted in an average time-savings of 4.4 minutes per Civet turbojet arrival aircraft. In fact, since the Dual Civet arrival procedures were implemented, there have been no national delay programs set up for the Airport, since delay has not been an issue. However, the Draft EIS/EIR does neither address nor incorporate the capacity or delay reduction efficiencies gained through this procedure in any of its modeling.²²

²² Where the Master Plan does address air traffic procedures, it is in error. The Master Plan states that the Departure Sequencing Program (DSP), a program that provides the capability to sequence departures from Los Angeles basin airports, would enhance capacity at the Airport. (Master Plan, § 2.6.1.3, page II-2.137) However, the DSP program has been cancelled by the FAA due to a lack of benefit. Essentially, the Southern California TRACON consolidation effort occurred many years ago and the references to it in the Master Plan and the Draft EIS/EIR are outdated. Many innovations and changes in airspace and procedures at the TRACON over the past few years have occurred, and none are referenced or adequately considered in the Draft EIS/EIR. Basically, the Draft EIS/EIR does not address the changes in airspace design or the new routes that have been developed as a result of airspace enhancements in Southern California.

Moreover, a closer examination of the Master Plan and the Draft EIS/EIR reveals that the Draft EIS/EIR may have ignored relatively inexpensive improvements in air traffic procedures in favor of very expensive, physical changes to the airfield. This is apparently because the Project's true purpose does not include the first two claimed in the Draft EIS/EIR, i.e., the broad ones of providing "sufficient airport capacity for passengers and freight in the Los Angeles region" (Draft EIS/EIR, Volume 1, page 2-1), in an "efficient and cost effective" way (Draft EIS/EIR, page 2-1). Instead, the Project's principal purpose is the narrow and singular one of accommodating "New Large Aircraft" ("NLA") that, with their long haul capabilities, would potentially serve the Airport in order to "sustain and advance the international trade component of the regional economy." (Draft EIS/EIR, page 2-1)²³

This conclusion is substantiated by the fact that the current aircraft fleet does not require 12,000 feet of runway to take off. Even today's heavy aircraft such as the B-747-400 and the B-777-400 only need 8,000 - 10,000 feet of runway for take-off and landing (under the weather conditions prevailing at the Airport). The Airport's existing runways are 8,295-feet, 10,285-feet, 12,091-feet, and 11,096-feet in length. Thus, even the shortest runway at the Airport can accommodate the heaviest and largest aircraft in the fleet under prevailing circumstances today.

The result of the Draft EIS/EIR's failure to acknowledge the Project's primary purpose, i.e., to increase the proportion of super long-haul aircraft in the fleet, is a concomitant failure to analyze the full range and magnitude of environmental impacts that may arise from the desired change in fleet mix. While it is, as yet, early in the NLA development process, some technical facts about the aircraft are already known, sufficient to make at least some educated projections concerning its impact. For instance, ascertaining the projected climb rate will enable an estimate of whether the NLA can meet current airport noise abatement operational requirements; or whether those will have to be altered; or whether the NLA will, ultimately, overfly noise sensitive communities at lower (or higher) altitudes, resulting in higher (or lower) noise levels over those communities. Similarly, preliminary data concerning engine type and emissions characteristics would

²³ The Draft EIS/EIR comes close to admitting as much: "Development of NLA aircraft is driven by increasing demand and constrained international gateway airports around the world, including LAX ... Development of the NLA will allow these airports to continue to meet the growing demand for travel between primary trading partners. As one of the three major (and busiest) gateway airports in the nation, LAX would be one of the first airports to be served by NLA." (Draft EIS/EIR, page 2-11)

enable at least a preliminary analysis of the air quality impact of the NLA, as well as the GSE needed to support it, if different from those categories already in use. Finally, the Draft EIS/EIR should have included the capacity/delay impacts from the increased use of NLA. As the Draft EIS/EIR fails to model ground operations in detail, the delay impacts that may result are not considered in developing an accurate analysis of arrival and departure flows and the congestion which may ensue even after Project implementation.

In summary, because the alternatives analysis is the “heart” of the NEPA process; because the Draft EIS/EIR fails to consider, or analyze, the impacts of eminently reasonable alternatives such as airspace changes to meet the Project’s stated purposes; because Alternative C does not alone meet the Project’s stated purposes; and because the most significant result of implementing Alternative C, the increased capacity to accommodate NLAs, remains unanalyzed from an environmental perspective, the Draft EIS/EIR’s alternatives analysis is seriously flawed.

VI. THE LAX MASTER PLAN AND DRAFT EIS/EIR FAIL TO SATISFY APPLICABLE LAW BECAUSE THEY DO NOT CONFORM TO OTHER RELEVANT PLANS.

Federal regulations require that all airport development conform to local plans. The FAA’s Airport Environmental Handbook clearly states that any airport plan must conform to the local air emissions plans:

“Section 176(c) of the Clean Air Act Amendments of 1977 states in part that no Federal agency shall engage in, support in any way or provide financial assistance for, license or permit, or approve any activity which does not conform to a State Implementation Plan after it has been approved or promulgated under section 110 of that Act. It is FAA’s responsibility to assure that Federal airport actions conform to state Plans for controlling area wide air pollution impacts.”

Airport Environmental Handbook, Chapter 5, p. 12. In addition, the Airport Environmental Handbook states that the 1982 Airport Act requires that Airport Improvement Program applications for projects involving airport location, runway location, or a major runway extension shall not be approved unless the governor of the state in which the project is located certifies that there is a “reasonable assurance” that the project will be located, designed, constructed, and operated in compliance with applicable air and water quality standards. Airport Environmental Handbook Chapter 5 p. 14. Finally, the FAA’s Airport Environmental Handbook states that all airport development must conform to local plans:

“For all airport development there shall be evidence to support the following Airport Improvement Program grant assurances as required by the 1982 Airport Act.

- (a) The project is reasonably consistent with existing plans of public agencies for development of the area (section 509(b)(1)(A));
- (b) Fair consideration has been given to the interest of communities in or near the project location (section 509(b)(4)); ...
- (d) Appropriate air and water quality certificates have been or will be obtained for projects involving airport location, runway location, or a major runway extension (section 509(b)(7)).”

Airport Environmental Handbook, Chapter 9, p. 3.

The LAX Master Plan and Draft EIS/EIR fail to conform to two key local plans. How the Master Plan and EIS/EIR fail to conform is discussed in the two paragraphs that immediately follow. However, it should be noted as an initial point that since the Master Plan and EIS/EIR fail to conform to two key local plans, they violate Section (a) referred to immediately above.

First, the LAX Master plan fails to conform to the relevant Air Quality Maintenance Plan. Mr. David Calkins, an expert in air emissions planning and compliance issues, reviewed the LAX Master Plan and Draft EIS/EIR. His reports are attached hereto as Exhibits “E” and “F”. In his report, Mr. Calkins states, “Review of Chapter 4.6 found several inconsistencies in LAWA’s reference to the conformity and SIP planning process.” Calkins Phase I Report, p. 11.

Second, Mr. Calkins has found that the Draft EIS/EIR fails to conform to the Regional Transportation Plan (“RTP”) in at least eight different ways. These differences are discussed in detail below. In addition to the Federal law requirements discussed above, under CEQA an EIR must discuss any inconsistencies between the proposed project and applicable general plans and regional plans. CEQA Guidelines § 15125(d). The Draft EIS/EIR fails to meet these requirements.

A. The LAX Master Plan Fails to Conform to the Air Quality Maintenance Plan.

The LAX Master Plan does not conform to the local air pollution reduction plan. Southern California is designated a “non-attainment area”²⁴ under the 1990 Clean Air Act.

²⁴ A “non-attainment area” has monitored air pollution levels in excess of the National Ambient Air Quality Standards (“NAAQS”).

Therefore all major projects must be constructed with assurance to the Federal Government that the project fits into the current air pollution reduction plan, known as the Air Quality Maintenance Plan (“AQMP”). See Calkins Phase II Report pp. 11-12. Mr. Calkins has determined that the LAX Master Plan Draft EIS/EIR fails to conform to the relevant AQMP in regards to the following:

1. Emission Inventory - the 2001 AQMP, currently in development, will require changes to the Draft EIS/EIR’s emission inventory.
2. Mitigation Measures - LAWA’s failure to commit to specific mitigation measures in the Draft EIS/EIR inhibits development of the 2001 AQMP.
3. Baseline Issues - use of the “adjusted” environmental baseline for off-airport traffic impacts does not allow comparison of the Draft EIS/EIR alternatives with current conditions, but actually compares the alternatives to a future condition.
4. Aircraft Mix - the Draft EIS/EIR assumes an aircraft mix of mostly jumbo airliners, in conflict with the adopted 2001 RTP calculations, which will cause differences in projected emissions between the Draft EIS/EIR and the AQMP.
5. Stationary Source Emissions - LAWA’s alternatives do not take into account the increase in nearby, off-airport stationary source emissions, despite LAWA’s assertions to the contrary; thus, it cannot conform to the regional plan.
6. Ground Support Equipment - LAWA failed to follow the California Air Resources Board’s (“CARB”) latest off-road emission model when concluding that emissions for future Ground Support Equipment would be zero.

Calkins Phase II Report at 13-14. These are serious conformance problems that must be first detailed, then remedied by LAWA before any action can be taken on the LAX Master Plan or its Draft EIS/EIR.

B. The LAX Master Plan Fails to Conform to SCAG’s 2001 Regional Transportation Plan.

The LAX Master Plan does not conform to the local Regional Transportation Plan (“RTP”). The Southern California Association of Governments (“SCAG”) is the main planning body for Southern California. At least every three years, SCAG adopts a RTP for the area, which sets forth its plan for the foreseeable future, usually 25 years. SCAG adopted a new RTP in April 2001. This RTP replaced SCAG’s previous plan, which was adopted in 1998. The Final RTP has not yet been formally released, but its contents in most areas relevant to LAX are known.

As discussed in the Calkins Phase II Report, attached as Exhibit F, the LAX Master Plan Draft EIS/EIR fails to conform to the RTP as follows:

1. Projected Passenger Load - the LAX Master Plan Draft EIS/EIR projects LAX handling over 92 million annual passengers (“MAP”) in 2015; the RTP limits LAX to handling what is considered to be its current physical capacity of 78 MAP.
2. On-Road Emissions Factors - The Draft EIS/EIR utilizes EMFAC2000, but the RTP uses emission factors based upon EMFAC7G. This inconsistency makes it quite difficult to compare the air quality impacts of the Draft EIS/EIR upon the RTP.
3. Different Model Years - The Draft EIS/EIR models years 2005 and 2015, but the RTP models 2025 as its model year.
4. Market Incentives - There are significant differences between the two plans in choice of market incentives, which causes potential conflicts between the two plans.
5. Aircraft and Passenger Characteristics - These differ in regards to projected aircraft types and passenger growth during the relevant periods.
6. Cargo Handling Projections - The Draft EIS/EIR projects much larger cargo handling for LAX than that planned for in the RTP.
7. High Speed Rail Projections - The Draft EIS/EIR rejects this project as too speculative, but the RTP bases projections on passenger and cargo demand in part upon the inclusion of this transportation mode.
8. Funding Projections - The RTP does not include the Ring Road, 105 Freeway extension, or 405 Freeway Connector Projects in its funding projections. The Draft EIS/EIR plans for funding of all these projects, presumably from Federal Highway funds.

Calkins Phase II Report at pp. 9-10.

LAWA’s failure to even discuss these issues is a serious deficiency in the Draft EIS/EIR. The Draft EIS/EIR cannot be acted upon until it is modified to conform to the RTP, assuming that is possible to do without simply scratching the entire analysis and starting over. If it is possible to salvage some small part of the plan, such as the mitigation measures, then the Draft EIS/EIR must be reissued for public comment.²⁵

²⁵ When new significant information becomes available after the public review period, Public Resources Code Section 21092.1 and CEQA Guidelines Section 15088.5 required

VII. THE DRAFT EIS/EIR DOES NOT ADEQUATELY SPECIFY MITIGATION MEASURES OR METHODS TO ENFORCE THEM.

CEQA requires that agencies identify the environmental impacts of a project, and implement mitigation measures to lessen the adverse environmental impacts. (CEQA Guidelines §15002 (a)(3)). However, the Draft EIS/EIR fails to comply with CEQA by (1) failing to provide a complete list of mitigation measures, and (2) failing to specify, at a minimum, a Draft Mitigation Monitoring Program to inform the public of how the project proponents intend to ensure the implementation of mitigation measures.

A. The Draft EIS/EIR Delays Disclosure of the Full List of Mitigation Measures Until the Final EIS/EIR.

CEQA Guidelines §15126.4(a)(1)(B) mandates that the “[f]ormulation of mitigation measures should not be deferred until some further time.” **While the Draft EIS/EIR acknowledges the existence of significant unmitigable impacts, it also states that, “A final package of design features, Master Plan Commitments, and Mitigation Measures will be developed ... The resulting Environmental Action Plan will be published in the Final EIS/EIR.”** (Draft EIS/EIR, Executive Summary, pg. ES-30) **By deferring to the Final EIS/EIR to reveal the mitigation measures, the public’s opportunity comment will have been attenuated.**

B. The Draft EIS/EIR Fails to Provide a Draft Mitigation Monitoring Program.

California Public Resources Code §21081.6 requires that a public agency “adopt a reporting or monitoring program for the changes made to the project or conditions of project approval, adopted in order to mitigate or avoid significant effects on the environment. The reporting or monitoring program shall be designed to ensure compliance during project implementation.” (Cal. Pub. Resources Code §21081.6 (a)(1)). If an EIR “identifies one or more significant environmental effects of the project,” CEQA Guidelines §15091(a) requires an agency to “make one or more written findings for each of those significant effects, accompanied by a brief explanation of the rationale for each finding.” With these findings, the CEQA Guidelines mandate that “the agency shall also adopt a program for reporting on or monitoring the changes which it has either required in the project or made a condition of approval to avoid or substantially lessen significant environmental effects. These measures must be fully enforceable through permit conditions, agreements, or other measures.” (CEQA §15091(d))

re-circulation of an EIR prior to certification.

The Draft EIS/EIR violates CEQA Guidelines §1509(d) and California Public Resources Code § 21081.6 in that it fails to set forth a program that monitors or reports on each mitigation measure. Although the Draft EIS/EIR cites some mitigation measures to combat the environmental impacts of the Project, it makes no mention of the “permit conditions, agreements, or other measures” (CEQA Guidelines § 15091(d)) which would ensure compliance with mitigation measures. In other words, it does not specify the steps necessary to ensure compliance, the responsible party to ensure compliance, or the resulting consequences should compliance not occur.

VIII. THE UNRELATED ISSUE OF “SAFETY” SHOULD NOT BE USED AS A SMOKE SCREEN TO PUSH THE CAPACITY-DRIVEN DRAFT EIS/EIR FORWARD.

In recent public statements, the FAA and LAWA have introduced the notion that because of its high number of runway incursions, the Airport is unsafe, and that the Project’s “improvements” are critical to remedying the adverse safety conditions.

Contrary to the FAA’s contention, however, runway incursions are largely a function of pilot or air traffic controller error, not airport layout and design.²⁶

²⁶ A pilot might enter a runway without proper authorization or clearance; a pilot is unfamiliar with an airport, does not hear an instruction, or fails to acknowledge an instruction to hold short of an active runway; a pilot, when approaching an active runway, crosses the hold line for that runway; a controller may clear an aircraft onto an active runway without ensuring that there are no other aircraft operating on that runway; the controller may fail to coordinate an aircraft crossing a runway with the controller who has the responsibility for approving all operations on that runway; a controller may clear an aircraft to cross a runway and the pilot may take an excessive amount of time crossing and may interfere with another aircraft; and the controller may fail to exercise the proper oversight of the operation and allow two aircraft to occupy an active runway resulting in a runway incursion.

In fact, the Airport can eliminate runway incursions only if it builds runways with no entrances and no exits. However, simple solutions such as enhanced marking and lighting for runways, increased awareness and training for pilots and controllers, improvements in communications and procedures, and resolving management issues at the FAA²⁷ are all basic and available measures that should be implemented at the Airport. In addition, affordable incursion-reducing technologies currently available to the Airport such as the Airport Movement Area Safety System (presently in use at the San Francisco International Airport), which uses radar to alert controllers to potential collisions, would minimize the problem as well.²⁸ In fact, even the FAA has even pressed the need for instituting technological improvements at airports to combat the runway incursion issue.²⁹

While recent incidents have made runway incursions a “hot button” in the eyes of the public, Congress, and aviation organizations, this recently surfaced “safety” issue cannot serve as justification for a project which otherwise fails to meet environmental standards.

²⁷ Transportation Department Inspector General Kenneth M. Mead recently told a House subcommittee that the “FAA’s director of runway safety has little authority over FAA employees who work on runway safety projects. Result: Almost every FAA runway safety project runs years late at more than double the anticipated cost, often failing to meet original expectations.” The Washington Post Company, “Runway Alert”, page A22, July 7, 2001.

²⁸ “It’s the first surface detection equipment that really gives an alert to the controller and allows the controller to prevent a collision.” CNN, “Close Calls on Runways Alarm Aviation Experts”, June 27, 2001.

²⁹ The Director of the FAA’s Runway Safety Office, Mr. Bill Davis, expressed that “he needs additional authority to coordinate and speed up technological improvements.” The Washington Post Company, “Runway Alert”, page A22, July 7, 2001.

IX. THE DRAFT EIS/EIR IS INSUFFICIENT AS A MATTER OF LAW BECAUSE IT DOES NOT SATISFY ENVIRONMENTAL JUSTICE REQUIREMENTS.

A. The Master Plan and EIS/EIR Unfairly Burden the Minority and Lower-Income Communities Surrounding LAX in Violation of Federal and California Law.

Federal law requires that each federal agency “make achieving environmental justice part of its mission by identifying and addressing, as appropriate, disproportionately high and adverse health or environmental effects of its programs, policies, and activities on minority populations and low-income populations.” Federal Actions to Address Environmental Justice in Minority Populations and Low-Income Populations” (Executive Order 12898, February 11, 1994). Environmental Justice is also a requirement of California law. Cal. Pub. Res. Code §72000-72001. Under California law Environmental Justice means “the fair treatment of all people of all races, cultures, and incomes with respect to the development, adoption, implementation and enforcement of environmental laws, regulations, and policies.” Cal. Pub. Res. Code § 72001. The California Environmental Protection Agency is charged with the responsibility to “[P]romote enforcement of all health and environmental statutes within its jurisdiction in a manner that ensures the fair treatment of people of all races, cultures, and income levels, including minority populations and low-income populations of the state.” Cal. Pub. Res. Code §72000(b). These requirements imposed on LAWA the responsibility to consider the impacts of LAX expansion on lower income and minority communities.

Several of the communities surrounding LAX, and to the east of LAX, in particular, contain predominantly minority populations and lower income populations. The Draft EIS/EIR contains a demographic analysis of the communities surrounding LAX that will be impacted by the LAX Master Plan. LAWA analyzed seventy census tracts, comprising parts of the City of Los Angeles, El Segundo, Inglewood, Hawthorne, and unincorporated areas of Los Angeles County. Draft EIS/EIR, Appendix F, Environmental Justice Technical Report, pp. 5-6. Fifty-four of the seventy census tracts within the study area are considered to be predominantly minority. A tract is so defined when more than fifty percent of the population is minority. *Id.* at 10.

Similarly, thirty-three of the seventy census tracts within the Impact Study Area are considered to be low-income. Low-income is defined as having more than 15% of the resident population below the poverty level. *Id.* Thirty-two of the thirty-three census tracts identified as low-income are predominantly minority. *Id.* at 15.

LAWA’s analysis shows that the distribution of minority and non-minority populations may cause differential impacts between these two groups:

“This data reveals a readily discernible pattern of minority and low-income communities in the areas surrounding LAX. While the areas to the north and south of LAX are predominantly non-

minority, the area east of I-405 within the study area is predominantly minority. Furthermore, within these areas east of I-405 minority populations are heavily concentrated: 39 of the 70 minority census tracts with the study area have minority percentages greater than 90 percent. The uneven distribution of minorities throughout the study area, as evidenced by the data showing that most census tracts have less than 20 percent or greater than 90 percent minorities, increased the potential for differential impacts on minorities and non-minorities.”

Id.

Minority and low-income populations are and have been disproportionately burdened by the impacts of LAX long before the massive expansion planned under the LAX Master Plan:

“[M]inority and low-income residential communities within the study area are currently concentrated east of LAX, separated from the airport by predominantly commercial and industrial airport-related land uses and the I-405 freeway. In contrast, residential areas of El Segundo and Playa Del Rey/Westchester, to the immediate north and south of the airport, do not have high concentrations of minority and low-income populations. LAX has always had an east-west runway configuration to take advantage of the prevailing wind pattern and to maximize efficient use of airspace. The combination of the long-standing runway orientation and more recent changes in the demographic patterns in the area around LAX means that minority and low-income residential communities are directly under the primary arrival flight path. The primary impacts on minority and low-income communities from current airport operations are therefore most associated with aircraft noise and air emissions. While residential areas of El Segundo and Playa Del Rey/Westchester directly adjacent to the airport are also exposed to high levels of side-line noise, the areas of exposure are much smaller in comparison to the noise-impacted residential communities to the east.”

Id. at 16.

Inglewood is one of the predominantly minority communities located east of LAX which receives a disproportionate share of the impacts of LAX. Inglewood’s population is 46.4% African-American, 46% Hispanic, 4.1% White, 1.6% Multi-racial, 1.1% Asian, 0.3% Pacific Islander, 0.2% Native American, and 0.2% Other. California Department of Finance, Demographic Research Unit, California State Census Data Center, Census 2000, “Table Two,

Population by Race/Ethnicity, Incorporated Cities by County, p. 5, attached hereto as Exhibit "A". In addition, a large percentage of the low-income census tracts in LAWA's study area are located in Inglewood. Draft EIS/EIR, Appendix F, Environmental Justice Technical Report, Figure 3, "Low-Income Census Tracts Within the Study Area."

LAWA's plan for massive expansion of LAX unfairly burdens the minority and lower-income communities surrounding LAX. LAWA failed to consider alternatives that would have shifted burdens away from minority or low-income populations, or that would at least have distributed the burdens and benefits of expansion more equitably. Instead of planning for massive expansion of LAX, LAWA should have considered alternatives to massive expansion of LAX.

LAWA admits that its Master Plan for expansion of LAX imposes a disproportionate burden of noise impacts upon persons of color and/or low income, and that it does not know if the Plan also imposes a disproportionate burden of toxic air emissions on those same groups. LAX Master Plan Draft EIS/EIR, Chapter 4.4.3 Environmental Justice, p. 4-395. As discussed in the report of Dale Hattis, PhD., attached hereto as Exhibit "B," if LAWA had chosen to seriously consider alternatives that did not include massive expansion at LAX, LAWA would have been able to consider alternatives that would reduce the human health risk overall and spread the environmental burden more equitably among the general population of Southern California. Hattis Report p. 3. Dr. Hattis observes:

"The framing of the options for analysis in the current draft is exclusively focused on engineering changes. Future "demand" for air services is estimated from a single set of assumptions about future population and economic growth in Southern California, and future national average costs of air travel in revenue per seat-mile, and then "build" options are designed to meet this projected "demand" either in full or in part. There is no apparent recognition or analysis of the possibility that at least some of the growth in "demand" for air services could be shifted to outlying airports downwind of major population concentrations (or out of the South Coast Air Basin entirely, in the case of connecting flights) by changes in economic pricing such as airport user fees. Such economic measures might not completely avoid the need to expand capacity at LAX, but they seem worthy of explicit consideration at least as supplements to the existing engineering options..."

Hattis Report p. 3.

For these reasons, LAWA should have considered alternatives to massive expansion of LAX. Dr. Hattis notes three specific reasons why such an analysis of alternatives should take place: (1) User fees, in addition to re-directing demand, could be used for mitigation measures;

(2) This approach would allow LAWA to slow growth at LAX, which would allow expansion at a much slower pace, which, in turn, will reduce congestion and, therefore, the significant impacts on the environment from construction; and (3) without such fees the real beneficiaries could be the airlines rather than the flying public. Hattis Report p. 3. LAWA should immediately and seriously consider other alternatives and analyze them to the same degree that it analyzed Alternatives A, B, and C in its current Master Plan. Anything less fails to adequately address Environmental Justice, as required by law.

B. The EIS/EIR Fails to Disclose LAWA's Economic Gain from the Proposed Expansion at the Expense of Surrounding Minority and Low Income Populations.

The LAX Master Plan Draft EIS/EIR fails to disclose the increased revenues that LAWA and the City of Los Angeles expect from the massive expansion plan, or that it comes at the expense of local low income and minority communities. As Dr. Hattis notes:

"[T]here are some glaring omissions of important effects from the economic impact analysis. Economic impacts are assessed in terms of changes in employment, and overall economic activity, for the South Coast as a whole, Los Angeles County, and the City of Los Angeles. Changes in on-airport employment are also described, as are the expected capital costs of the various policy options. Unaccountably, there does not seem to be any readily locatable presentation of expected effects on operating revenues and costs for the major economic actors that are directly affected by the proposed project LAWA itself, the City of Los Angeles as owner and taxing authority, and the airlines. Projections of these expected impacts must exist. Moreover, they are highly relevant to judgments of the equity (fairness) of the distribution of expected good and bad effects on the different policy options for different groups, including an expanded Environmental Justice analysis."

Hattis Report p. 6.

LAWA and the City of Los Angeles stand to reap tremendous financial benefits from LAX expansion. Since these benefits are not specified, the comparative benefit to local low income and minority communities--or the lack thereof--cannot be and has not been evaluated. LAWA must disclose these figures for a meaningful analysis of the relative benefits and burdens to be considered.

C. The Master Plan Creates a Disproportionate And Unfair Distribution of Incremental an Total Direct Job Impacts.

The LAX Master Plan does not fairly distribute new jobs among local minority and low-income communities. According to LAWA's own economic analysis, cities in the "Primary LAX Area" (El Segundo, Hawthorne, Inglewood, Del Aire and Lennox) receive only 3.8% of the incremental "direct jobs" at LAX due to expansion. LAX Master Plan Draft EIS/EIR, Economic Impacts Technical Report, Table 46, "Distribution of Incremental Direct Job Impacts of the LAX Master Plan Alternatives, By County and City, 1996-2015", p. 95. This same area also receives only 3.4% of the total direct job impacts from LAX in 2015. LAX Master Plan Draft EIS/EIR, Economic Impacts Technical Report, Table 47, "Distribution of Total Direct Job Impacts of the LAX Master Plan Alternatives, By County and City, 2015," p. 96. Compared to the year 1996, the City of Inglewood shows a net increase of only 489 jobs in "LAX- Related Employment" if LAWA adopts Alternative C. LAX Master Plan Draft EIS/EIR, Economic Impacts Technical Report, Table 48, "LAX-Related Employment in the South Bay and North Bay Cities and Communities For the LAX Master Plan EIS/EIR Alternatives, 1996, 2005, and 2015," p. 97. Conversely, the environmental burdens of LAX fall most directly upon those living in its immediate vicinity, like Inglewood. LAWA should make firm commitments to take all reasonably practical steps to ensure that a proportionate share of the economic benefits of LAX also reach those communities. Under the LAX Master Plan, according to LAWA's own jobs projections, that does not occur.

D. The Economic Benefits Of The LAX Master Plan Are Not Proportionate to the Environmental Burdens it Imposes on Surrounding Minority and Low Income Communities.

LAWA should share the economic benefits that flow from LAX with the surrounding communities to the same degree that the environmental burdens are borne by those communities. Offsetting environmental burdens with economic benefits is an important part of Environmental Justice: "In making determinations regarding disproportionately high and adverse effects ... mitigation and enhancement measures ... and all offsetting benefits to the affected minority may be taken into account." Department of Transportation Order 5610.2 -Actions to Address Environmental Justice in Minority Populations and Low-Income Populations, April 15, 1997. Firm commitments in this regard should be made by LAWA in the Draft EIS/EIR. For example, regarding increased cargo capacity at LAX, the Draft EIS/EIR states:

"It is possible that some of the increased demand [for cargo handling] could be met nearby in Inglewood where the City's General Plan indicates a priority for expanding existing industrial firms and providing increased employment opportunities while mitigating residential areas significantly impacted by aircraft noise."

Draft EIS/EIR "Induced Socio-Economic Impacts," Section 4.5, page 4-446.

Although it acknowledges the potential symbiosis of cargo expansion for LAWA and Inglewood, the Draft EIS/EIR fails to incorporate a reasonable and proportionate distribution of

the economic benefits of LAX expansion. If the burdens of LAX expansion are to be thrust upon the City of Inglewood, fair treatment requires that efforts be made to direct potential benefits to the communities impacted by those effects--effects that are significant and cannot and will not be mitigated. The proposed redevelopment along Century Boulevard is a good first step in this direction; however, more needs to be done. LAWA should make concrete commitments to address this issue, and its failure to do so renders the EIS/EIR insufficient as a matter of law.

X. THE DRAFT EIS/EIR FAILS TO SATISFY APPLICABLE LAW BECAUSE IT IMPROPERLY MEASURES HUMAN HEALTH RISKS.

A. LAWA's Study does not Adequately Factor Time as a Variable.

LAWA analyzes environmental health impacts for two years - 2005 and 2015; however, the environmental health impacts will occur over time. Accordingly, LAWA's analysis inaccurately minimizes certain risks and fails to consider numerous cumulative impacts.

Further, as noted by Dr. Hattis, "2005 does not represent even the peak year for construction-related impacts." Hattis Report p.4. In fact, emissions of particulate matter in year 2004 are expected to be more than twice those in 2005 (approximately 44,000 lbs/day versus 19,000 lbs/day). For a proper analysis, LAWA should "analyze and express impacts in terms of both peak-year and integrated bottom-line measures of effect over a reasonably foreseeable extended time over which the facilities will be built and operated." Hattis Report p. 4.

B. The Draft EIS/EIR Fails to Adequately Delineate Health Risks.

The increased health risks associated with the LAX Master Plan should be set forth with more clarity and specificity in the Draft EIS/EIR. Impacts are expressed primarily in terms of "significance" of effects for the most exposed individual, or, when considering certain carcinogenic effects, in terms of the areas or numbers of people exposed to concentrations expected to exceed a 1/100,000 lifetime incremental cancer risk criterion or an unusual criterion for non-cancer effects of a hazard index of 5. Hattis Report p. 4. However, the usual criterion used in many impact assessments under other environmental statutes, including Superfund, is a hazard index of 1.5.³⁰ Id. Dr. Hattis notes:

³⁰ The difference between a hazard index of 1 and 5 is fivefold in the toxicity-weighted concentrations of the pollutants covered by the index in terms of risk. The fraction of people who suffer irritation and other non-cancer effects is likely to be larger than fivefold, depending on the shape of the dose response relationship.

"These ways of expressing health impact results are of some relevance because they help the audience judge the fairness of the burden of extra risk imposed for residents of the areas most affected by the project options. However, exclusive definition of impacts in terms of the area or number of people who receive an increment of risk or (for non-carcinogenic agents) exposure to pollutants from LAX-related sources alone that is deemed to exceed a single bright line of 'significance' ignores the incremental cancer and non-cancer risks to people who do not happen to be moved across such a criterion level. Further, these ways of summarizing impacts can not, by themselves, give decision-makers and the public a sufficient description of the overall health impacts to arrive at a reasoned judgment of whether the mix of economic, human health, and environmental impacts of the proposed "build" option is more desirable overall than the comparable impacts of other options. The current analysis of economic activity describes projected aggregate changes in jobs and overall economic activity for the City of Los Angeles, Los Angeles County, and the whole Southern California area. To be comparable with these aggregate economic impacts, aggregate measures of health impacts must be created and the current artificial limitation of the study area for quantifying air pollution impacts must be transcended."

Hattis Report pp. 4-5.

Decision-makers and the public should be informed of the differences among options in overall cases of cancer that are expected to arise over the lifetimes of the individuals exposed over particular periods of construction and operation of the proposed facilities. This should be done for the entire geographic area of the South Coast Air Basin that receives incremental changes in exposures. Hattis Report p. 5. Human health impacts can and should be expressed in aggregate incremental cancer cases, aggregate incremental deaths, aggregate incremental hospitalizations and aggregate incremental asthma effects for the entire Los Angeles basin associated with the LAX Master Plan. Hattis Report p. 5. These calculations are certainly feasible and would inform the decision makers and the public of the true human health effects of the project. Until this is done, the document is deficient in addressing this topic.

C. The Draft EIS/EIR Fails to Consider Health Risks on a Regional Basis.

The Draft EIS/EIR's human health risk assessment should study risks created by the Master Plan in the entire Southern California region, not simply in those areas immediately surrounding LAX. Failure to do so conceals the advantages in terms of health risks from expanding other airports instead of LAX. As Dr. Hattis notes:

"Were the analysis expanded to include some options shifting additional air service to outlying airports (as recommended above), continued use of the more localized health impact analysis method would cause analysts to miss important benefits that would accrue from placing emissions downwind rather than upwind of the major population centers of the Los Angeles area."

Hattis Report p. 5. Restricting the environmental impact analyses to the immediate LAX area and the options considered only to expansion of LAX prevents considering the relative burdens of LAX expansion on minority and lower-income communities versus expansion of air service at other airports. The City of Inglewood appears to be substantially included in the existing boundaries of the air dispersion modeling study, but it is important to have impacts broken down by various political jurisdictions covering the most affected communities. Hattis Report pp. 5-6. LAWA's current approach on this risk assessment fails to fully capture all relevant data.

D. LAWA Failed to Conduct a Sensitivity Analysis of Its Human Health Risk Assessment.

LAWA failed to conduct a sensitivity analysis of its health risk assessment. This failure means that the health risk assessment does not attempt to assess and communicate uncertainties in a quantitative way. Whether through sensitivity analysis, or use of a more sophisticated model, such analysis can be and is used to inform interested parties of the uncertainties in key results. Hattis Report p. 6. One aspect of the modeling that needs such analysis is the assumed behavior responses of airlines to increasing delays as the intensity of usage of airport facilities increases. *Id.* This variable affects "capacity" calculations, emissions estimates and economic results. LAWA should perform such sensitivity analysis of its methods and conclusions.

XI. CONCLUSIONS.

Based on the above analyses, the Draft EIS/EIR does not serve its most fundamental purpose as an "environmental alarm bell" to "alert the public and responsible officials to environmental changes before they have reached ecological points of no return." (See, e.g., County of Inyo v. Yorty, 32 Cal.App.3d 795, 810 (1993).) Among other things, the varying baselines, selectively applied to areas of potential impact so as to artificially diminish the apparent impacts of the Project; and the lack of consideration of imminently reasonable alternatives, including air traffic alternatives, to the expenditure of billions of dollars in what are ultimately only marginally effective airfield improvements, require substantial analytic revisions to the Draft EIS/EIR. Absent further revision of the analyses set forth in the Draft EIS/EIR as set forth above (Center Sensible Planning, Inc. v. Board of Supervisors, 122 Cal.App.3d 813, 822 (1981)), the public will have been denied its statutorily mandated opportunity to test, assess and

evaluate the new data and conclusions contained in the Draft EIS/EIR, and to make informed judgments as to their validity, in direct contravention of CEQA requirements.

TABLE OF CONTENTS

	<u>Page</u>
INTRODUCTION	2
DISCUSSION	3
PART ONE - THE ENVIRONMENTAL JUSTICE ANALYSIS OF THE SUPPLEMENT TO THE DRAFT EIS/EIR VIOLATES CEQA	3
1. The SEIS/EIR Is Bound By Environmental Justice Considerations	3
2. Alternative D Unfairly and Disproportionately Burdens Minority Schools	3
a. Significant impact of increased noise on education in Inglewood Unified School District schools	4
b. Significant impacts of increased noise on students, teachers, staff and administration	5
c. Significant impacts of increased pollution on students, teachers, staff and administration	6
3. The SEIS/EIR Violates CEQA By Failing to Consider Alternatives that Equitably Distributes Burden Among Populations	8
4. The SEIS/EIR Violates CEQA By Failing to Provide Mitigation Measures for the Significant Environmental Justice Impacts	8
PART TWO - THE SEIS/EIR IMPROPERLY RELIES UPON AND OVER ESTIMATES THE EFFECT OF THE SETTLEMENT AGREEMENT	9
1. The SEIS/EIR Fails to Consider All Possible Surcharges on the Avigation Easements	10
2. The Impacts of the Alternate D Will Constitute a Surcharge on the Avigation Easements	11
3. The Existence of the Settlement Agreement is Irrelevant to Whether LAWA Must Comply With CEQA	12
PART THREE - THE NOISE ANALYSIS OF THE SEIS/EIR IS INADEQUATE	14
1. The SEIS/EIR Under-Predicts Noise Impacts to Inglewood Unified School District Facilities By Omission	14

2.	The SEIS/EIR Under-Predicts Noise Impacts to Inglewood Unified School District Facilities by Relying on Noise Modeling Results Which Are Acknowledged Within the Report to under-Predict Actual Aircraft Noise Levels	15
3.	The “Single Event” Noise Analysis Presented in the SEIS/EIR is Incomplete	15
4.	The Limited ‘Single Event’ Noise Analysis Presented in the SEIS/EIR Substantially Under-Predicts Impacts to Inglewood Unified School District Facilities in a Number of Ways	15
a.	The indoor classroom L_{max} thresholds are set too high	15
b.	Classroom interior noise levels based upon assumed 29 dBA out-to-in aircraft noise reduction do not adequately protect a large enough proportion of classroom users in the Inglewood Unified School District	16
c.	The SEIS/EIR’s proposed 84 dBA L_{max} outdoor single event noise threshold is too high to assess single event noise impact upon classrooms, leading to a severe under-reporting of existing and future noise impacts	17
d.	The main body of the SEIS/EIR should consider significantly increased cumulative duration to excessive noise levels as a significant noise impact	18
5.	The Project Alternatives Included in the EIS/EIR Do Not Appear to Satisfy CEQA or NEPA Requirements	20
6.	The Analysis of Temporary Aircraft Noise Impacts Is Inadequate	20
7.	Inadequate/Mislabeled Data in Supplemental Aircraft Noise Technical Report	21
8.	Specific Noise Mitigation Measures for Inglewood Unified School District Facilities Are Not Clearly Stated in the SEIS/EIR	21
a.	The SEIS/EIR’s analysis of the health effects of noise on students is flawed	21
i.	The SEIS/EIR improperly relies on a flawed FICON document	21
ii.	The SEIS/EIR Ignores the Scientifically Confirmed and Well Established Link Between Noise Exposure and Children’s Learning	23
iii.	The SEIS/EIR Entirely Neglects the Substantiated Link Between Noise and Other Adverse Learning and Health Effects on Children	24
b.	The SEIS/EIR’s Proposed Noise Study is Inadequate	25

i.	LAWA May Not Postpone Its Proposed Noise Study Absent a Commitment by LAWA to Mitigate	25
ii.	A Deferred Noise Analysis Is Inappropriate	26
iii.	Failure to Conduct a Study Prior to Publishing the SEIR/EIR Is Against Public Policy	26
iv.	The Proposed Noise Study Must Meet Stringent Scientific Standards to be Valid	27

PART FOUR - THE EMISSIONS, MODELING, MITIGATION MEASURES AND HEALTH IMPACT ANALYSIS OF THE SEIS/EIR IS INADEQUATE 30

1.	The Emissions Estimations In The SEIS/EIR Violate CEQA	30
a.	Jet Aircraft Emission Estimates May Be Underestimated As The Methodology Used To Estimate Particulate Emissions From Jet Aircraft Is Unclear And May Be Flawed	30
b.	Potentially significant evaporative emissions of toxic air contaminants resulting from the storage and handling of organic liquids may not have been quantified	31
2.	The Modeling Approach of the EIS/EIR Violates CEQA	32
a.	The methodology used to estimate plume rise from jet aircraft is questionable and requires further justification	33
b.	The assumption that building downwash is negligible requires further justification	33
c.	The meteorological data set used is inadequate relative to EPA recommendations	34
d.	Atmospheric conversion of sulfur dioxide to sulfate may be significant and is not addressed	34
e.	Secondary formation of toxic air pollutants may be significant and is not addressed	35
f.	The exclusion of deposition effects from the multipath risk analysis is not justified	36
3.	The Mitigation Measures Proposed By The SEIS/EIR Violate CEQA	37

a.	The mitigation measures proposed in the SEIS/EIR have not met all requirements outlined in the SCAQMD CEQA Handbook	37
b.	Mitigation measures, except those specific to construction activities, should be applied towards the No Action/No Project alternative in addition to Alternatives A, B, C, and D	37
4.	The Health Risk Analysis of the EIS/EIR Violate CEQA	39
a.	Estimated cumulative cancer risks to school children have been underestimated due to underestimates in the total number of years children spend in school	39
b.	Significant flaws in the methods used to calculate cumulative cancer risks and noncancer hazards undermine the conclusions of the EIS/EIR and obscure actual health risks posed by the various alternatives	40
c.	The basis for significance threshold for noncancer health effects is unclear and five times greater than the threshold typically used by regulatory agencies	41
d.	The EIS/EIR fails to consider and evaluate the potential health impacts associated with exposure to lead	42
e.	Excluding particulate emissions from jet aircraft from the quantitative risk evaluation could significantly underestimate the potential for noncancer health impacts	43
f.	Absolute cancer and noncancer risks are not presented in the EIS/EIR	44
g.	The EIS/EIR does not consider child-specific noncancer toxicity criteria which have been proposed by the State of California and are intended for use in the risk assessment of California school sites. Noncancer health risks to school children may be underestimated accordingly	45
h.	Use of 1996 as basis for determining project significance is not explained and seems illogical	45
i.	Methodology for establishment of baseline (1996) impacts is poorly defined and highly suspect. All determinations of significance of Alternative D through comparison to 1996 baseline impacts are therefore questionable	46
j.	Alternative D post-mitigation incremental cancer risk to adult residents may be greater than 10 per million individuals	46

k.	Statement that acrolein noncancer risks are substantially overestimated in the EIS/EIR analysis is not supported by the arguments presented	47
l.	Use of different receptor/grid spacing when calculating pre- and post-mitigation impacts prevents assessment of mitigation effectiveness	47
	PART FIVE - THE TRAFFIC IMPACT ANALYSIS IS INADEQUATE	48
1.	Lennox Interchange	48
2.	Other Considerations	49
a.	Freeway Avoidance Traffic	49
b.	Construction	49
c.	Phasing	49
	PART SIX - THE ENROLLMENT IMPACT ANALYSIS IS MISLEADING	50
	PART SEVEN - THE SUBSTANTIAL SHIFT IN PROJECT OBJECTIVES REQUIRES LAWA TO EXAMINE AN ADEQUATE RANGE OF PROJECT ALTERNATIVES ...	51
	PART EIGHT -THE EIS/EIR VIOLATES CEQA READABILITY REQUIREMENTS .	52
a.	Original EIS/EIR	52
b.	Addition of Supplement to the EIS/EIR	53
	CONCLUSION	53

INTRODUCTION

On September 21, 2001, the Inglewood Unified School District submitted its response to the original Los Angeles International Airport ("LAX") Draft Environmental Impact Statement/Environmental Impact Report ("Original EIS/EIR"). The Inglewood Unified School District now respectfully submits its Response to the Supplement to the Draft LAX Environmental Impact Statement/Environmental Impact Report ("SEIS/EIR") prepared by the City of Los Angeles, Los Angeles World Airports ("LAWA") and the Federal Aviation Administration. (The Original EIS/EIR and SEIS/EIR are referred to collectively as "EIS/EIR".)

Pursuant to applicable provisions of the California Environmental Quality Act ("CEQA") and the National Environmental Policy Act ("NEPA"), due to its proximity to LAX and the significant environmental impacts LAX has upon Inglewood schools, the Inglewood Unified School District is an interested party with whom LAWA must consult regarding the SEIS/EIR. (14 *California Code of Regulations* § 15086(a)(4).) Accordingly, the Inglewood Unified School District reviewed and analyzed the SEIS/EIR as well as retained qualified experts in the fields of aircraft noise assessment, the effects of noise on human health, behavior and learning, air emissions, regulation and planning, human health risk assessment, traffic engineering and planning, public policy, environmental and real property law. The work product of these experts is incorporated in the body of this Response.

Although the Inglewood Unified School District has undertaken the task of providing this Response, it believes it to be procedurally incorrect and financially unfair for a school district of extremely encumbered financial resources to be burdened with the costs of conducting the initial research and analysis required to be in the SEIS/EIR but omitted.

To the extent new facts and issues are raised in the SEIS/EIR, the Inglewood Unified School District provides its Response below. To the extent that the SEIS/EIR relies upon or is consistent with the Original EIS/EIR, the Inglewood Unified School District incorporates its September 21, 2001 Response and Comments by reference herein. This Response also incorporates the exhibits from the September 21, 2001 Response, and continues numbering the exhibits from that document.

Based upon its review and analysis of the Original EIS/EIR and the SEIS/EIR, the Inglewood Unified School District respectfully submits the EIS/EIR fails to satisfy the requirements of either CEQA or NEPA. Accordingly, the Inglewood Unified School District respectfully requests LAWA substantially revise its EIS/EIR to: (1) include additional alternatives that address LAWA's new paramount safety and security objectives; (2) specifically address the impacts of the Alternative D discussed herein, as well as the other alternatives contained in the Original EIS/EIR; and (3) provide for proposed mitigation at Inglewood Unified School District schools for the benefit of the disproportionately affected children in attendance.

DISCUSSION

PART ONE

THE ENVIRONMENTAL JUSTICE ANALYSIS OF THE SUPPLEMENT TO THE DRAFT EIS/EIR VIOLATES CEQA

All of the alternatives presented by LAWA in its EIS/EIR, including Alternative D presented in the SEIS/EIR, disproportionately impact minorities. The students of the Inglewood Unified School District receive an unfair share of the burdens of Alternative D, including educational and health impairments.

1. The SEIS/EIR Is Bound by Environmental Justice Considerations.

LAWA is mandated by federal and state law to identify and address environmental justice issues in its environmental review. *Executive Order 12898* requires that each federal agency "make achieving environmental justice part of its mission by identifying and addressing, as appropriate, disproportionately high and adverse health or environmental effects of its programs, policies, and activities on minority populations and low-income populations." ("Federal Actions to Address Environmental Justice in Minority Populations and Low-Income Populations," *Executive Order 12898*, February 11, 1994, Exhibit 15.)

State law similarly requires consideration of environmental justice issues in environmental impact reports. (California *Public Resources Code* § 71110 *et seq.*) The California Environmental Protection Agency is obligated to "[p]romote enforcement of all health and environmental statutes within its jurisdiction in a manner that ensures the fair treatment of people of all races, cultures, and income levels, including minority populations and low-income populations of the state." (California *Public Resources Code* § 71110(b).)

Thus, the SEIS/EIR must (1) identify disproportionate, adverse environmental and health effects on minority and low income populations and (2) present mitigation measures to alleviate the unfair effects of its project alternatives upon minority and low income populations.

2. Alternative D Unfairly and Disproportionately Burdens Minority Schools.

The Southern California Association of Governments concluded in its 2001 Regional Transportation Plan, ". . . limiting further expansion of LAX is the best possible Plan outcome from an environmental justice perspective. This is due to the relatively high concentration of low-income and minority populations in the vicinity of LAX."

The SEIS/EIR admits the following:

"Effects on public schools associated with aircraft noise exposure would fall on schools that are located predominantly within minority and/or low-income communities . . . [U]nder Alternative D, three public schools would be newly exposed to 65 CNEL or greater aircraft noise levels or exposed to an increase of 1.5 dBA

or greater within the 65 CNEL contour by 2015. These schools (Beulah Payne Elementary School, Hillcrest Continuation School, and Inglewood High School) are all within minority and/or low-income areas and are within the Inglewood Unified School District. Furthermore, based on a supplemental analysis of classroom disruption ..., three public schools (Beulah Payne Elementary School, Inglewood High School, and Morningside High School) would be exposed to noise levels that could be disruptive to classroom activities which are similarly located within minority and/or low-income areas and are within the Inglewood Unified School District. Therefore, Alternative D would have a disproportionate effect on minority and/or low-income communities with regard to schools that are newly exposed to aircraft noise and schools that are exposed to high single event noise levels." (SEIS/EIR, *Environmental Justice*, Section 4.4.3, p. 4-324.)

Given the acknowledged burden placed on the schools which are impacted by Alternative D, options that address the situation need to be set forth in the EIS/EIR.

a. Significant impacts of increased noise on education in Inglewood Unified School District schools.

As with the alternatives proposed in the Original EIS/EIR, Alternative D would have a significant adverse impact on the education of students in the Inglewood Unified School District. Table S17 of the *Supplemental Aircraft Noise Technical Report* of the SEIS/EIR presents data which provides an indication of the time that the increased airplane overflights under Alternative D will take out of each school day. When considering these numbers, it is important to note that, not only does the interruption lasts at least six seconds (SEIS/EIR, *Noise*, Section 4.1.6.1.5.4.2, p. 4-66), but there is anticipation time as the deafening noise immediately approaches, as well as time spent settling back into instruction after the disruption has receded.

For example, Table S17 suggests Beulah Payne Elementary School will lose a total of 12.1 minutes of instructional time each day once Alternative D is implemented. What real impact will this 12.1 minutes have on actual instruction? Approximately 40 times per day, instruction, reading and/or test taking will be stopped or interrupted in the classrooms at this school.¹

Under Alternative D, at Inglewood High School and Morningside High School, the impact is worse - instruction will be interrupted at least 45 times per day.

¹ Assuming overflights occur at a constant rate over a 24 hour day (which, of course, they do not - rather they occur more frequently during the time of instruction): 12.1 minutes = 726 seconds; 726 seconds divided by 6 second intervals = 121 occurrences; 121 occurrences divided by 24 hours = 5 occurrences per hour; 8 hours of instruction during the day = 40 occurrences per day during the time of instruction.

Moreover, Oak Street Elementary School suffered from an unimaginable 140 interruptions of instruction per day - - over 17 per hour - - in 1996. Children in classes have consistently had to disengage and reengage to classroom instruction, or simply failed to hear the teacher, every few minutes during each and every class, every day of school. This is, of course, a conservative extrapolation - - the actual number of classroom interruptions is probably far higher. This already inordinate number of classroom interruptions increases under Alternative D.

A total of 33.9% of the students in the Inglewood Unified School District are "English Learner" students, who are not proficient in English. (Education Data Partnership ("Ed-Data"), "Fiscal, Demographic, and Performance Data on California's K-12 Schools," <http://www.ed-data.k12.ca.us>.) Additionally, 68.8% of students at Beulah Payne Elementary School and 57% of the students at Oak Street Elementary School do not speak English as their first language. (*Id.*)

These noise interference numbers are substantially similar to those suggested by Table S31, *Supplemental Aircraft Noise Technical Report*, Section 6.2.2, p. 151.

In surveys of Inglewood Unified School District teachers and staff, the vast majority stated that the current airplane noise levels substantially interfere with their teaching; that students are frequently distracted by the aircraft noise; that the schools' outdoor activities are frequently disrupted by the aircraft noise; and that aircraft noise is a "significant problem" at their schools. (Gerson/Overstreet Architects, *Draft Final Report: Noise Impact Analysis Study and Mitigation Measures*, December 5, 2000, Original EIS/EIR Response Exhibit 1.) These educational impacts will only worsen with implementation of Alternative D.

b. Significant impacts of increased noise on students, teachers, staff and administration.

As noted by the World Health Organization, noise interference with speech comprehension results in a large number of personal disabilities, handicaps and behavioral changes. Children in the process of language and reading acquisition are noted to be particularly vulnerable. Problems with behavior, concentration, fatigue, uncertainty and lack of self-confidence, irritation, misunderstandings and a decrease in work capacity have been reported by researchers. (World Health Organization, *Environmental Health Information, Guidelines for Community Noise*, "Adverse Health Effects of Noise," Section 3, April 2001, Original EIS/EIR Response Exhibit 2.)

A study conducted in 1976 in Highline School District looked at the relationship between school test scores for school grades 3-7 and 5-10 for children attending schools exposed to high levels of aircraft noise and other children attending quiet schools. (Maser, A. L., Sorensen, P.H., Kryter, K.D., and Lukas, J.S. *Effects of Intrusive Noise on Classroom Behavior: Data From a Successful Lawsuit*. West. Psychol. Assoc. San Francisco. April 1978, Original EIS/EIR Response Exhibit 3.) While high academic-aptitude students in schools exposed to aircraft noise scored as well in standardized tests as their counter-parts in quiet schools, middle and especially low academic-aptitude students in noisy schools showed progressive deterioration in tests with continued school attendance relative to the students of equal aptitude in quiet schools. (*Id.*)

A study of the impact of various levels of freeway noise on reading test scores highlighted the cumulative adverse effect of noise exposure on school children. (Lukas, J.S., DuPree, R.B. and Swing, J.W. *Effects Of Noise On Academic Achievement And Classroom Behavior*. FHWA/CA/DOHS-81/01 Office of Noise Control, California Dept. Of Health Services, Sacramento. 1981, Exhibit 16.) An apparent degradation in reading achievement with classroom noise that was noted for third-graders, was accelerated by the sixth grade. (*Id.*)

Other research has demonstrated the link between chronic exposure to aircraft noise and many adverse effects including learning, motivational deficits, a significant decrease in total quality of life, increase in psychophysiological stress and susceptibility to helplessness. (Gary Evans and Lorraine Maxwell, "Chronic Noise Exposure and Reading Deficits. The Mediating Effects of Language Acquisition." *Environment and Behavior*, Vol. 29 No. 5, September 1997 [learning deficits], Original EIS/EIR Response Exhibit 4; Cohen S., Krantz, D.S., Evans G.W., Stokols D., and Kelly S., "Aircraft noise and children: Longitudinal and cross-sectional evidence on adaptation to noise and the effectiveness of noise abatement." *J. Pers. Soc. Psychol.* 40: 331-345, 1981 [learning deficits], Exhibit 17; Bullinger, M., Hygge, S., Evans, G.W., Meis, M. and von Mackensen, S., "The Psychological Cost of Aircraft Noise for Children," *Zentralblatt fur Hygiene und Umweltmedizin*, 202:127-138, 1977 [quality of life decrease], Original EIS/EIR Response Exhibit 5; Gary W. Evans, Monika Bullinger and Staffan Hygge, "Chronic Noise Exposure and Physiological Response: A Prospective Study of Children Living Under Environmental Stress." *Psychological Science*, Vol. 9, No. 1, January 1998 [psychophysiological stress], Original EIS/EIR Response Exhibit 6; World Health Organization, *Guidelines, supra.* [helplessness].)

A 1980 study showed elevated blood pressure of children attending schools under the LAX flight paths compared to children in quiet schools. (Cohen S., Krantz, D.S., Evans G.W. and Stokols D., "Physiological, motivational, and cognitive effects of aircraft noise on children: Moving from the laboratory to the field." *American Psychologist*, 35: 231-243, 1980, Exhibit 18.)

The SEIS/EIR does not suggest that conditions resulting from implementation of Alternative D will result in different circumstances than those discussed in the above-referenced studies. Again, the SEIS/EIR fails to provide for any remediation for the known impacts of Alternative D on Inglewood Unified School District students.

c. Significant impacts of increased pollution on students, teachers, staff and administration.

As noted by the United States Environmental Protection Agency ("USEPA"), exposure to ambient criteria and toxic pollutants resulting from anthropogenic emissions can result in a wide variety of health impacts. (USEPA, *The Benefits and Costs of the Clean Air Act, 1970 to 1990*. Prepared for U.S. Congress, October 1997, Original EIS/EIR Response Exhibit 7.) Short-term health impacts can include eye, nose, and throat irritation; losses in hand-eye coordination (compensatory tracking); vigilance (detection of infrequent events); visual system sensitivity; and increased asthma attacks. (Seinfeld, John H., *Atmospheric Chemistry and Physics of Air Pollution*. New York, John Wiley & Sons, 1986.) Long-term exposures can result in increased

mortality, susceptibility to pulmonary bacterial infection, irritation of the alveoli, emphysema, chronic bronchitis, reduced pulmonary function, losses in IQ, and cancer. (*Id.* and USEPA, *Benefits, supra.*)

Furthermore, there is good reason to believe that children could be more vulnerable to these effects. Because of growing concerns regarding children's increased susceptibility to environmental contaminants, the California Legislature passed the Children's Environmental Health Protection Act (SB 25), which requires the California Environmental Protection Agency ("Cal/EPA") to specifically consider children in setting Ambient Air Quality Standards and developing criteria for Toxic Air Contaminants ("TACs"). The law will require Cal/EPA to specifically evaluate available information on children's increased susceptibility to each of the TACs, and develop a list of up to five TACs that potentially have disproportionate impacts on infants and children.

As stated by Cal/EPA, children are considered to be at increased risk because of the rapid growth and development of their nervous, immune and reproductive systems, and because their organs and tissues are rapidly maturing. (Cal/EPA, *Air Pollution and Children's Health*. Fact Sheet by Office of Environmental Health Hazard Assessment, March 2001, Original EIS/EIR Response Exhibit 8.) In addition, children experience greater exposure to ambient pollutants relative to their body weight, and children's specific activity patterns may contribute to an increased exposure to toxicants resulting from increased exercise and sporting activities. (*Id.*) Asthma has also been identified as a major problem in children, and some of the chemical emissions from LAX have been identified by Cal/EPA as resulting in an exacerbation of asthma (e.g., formaldehyde and acrolein). (*Id.*)

Furthermore, recent studies suggest that particulate matter ("PM") may exacerbate asthma and cause coughs and other respiratory symptoms in children. (*Id.*) Recent studies also suggest that prolonged exposure to PM may also affect the growth and functioning of children's lungs. (*Id.*) Researchers found that as children grow up in smoggier areas, there is a notable lag in lung function growth. (*Id.*)

Because of the anticipated environmental and related health impact of noise and pollution on the schools, students could potentially fall behind in their schooling, one class grade or more. Several students could have an impaired ability to retain information as a result of the impact. These students may not be able to grasp as much as other students and would not be able to process more advanced concepts taught in high school that build upon what they were supposed to, but did not, learn in elementary school. More children would have asthma and allergies than they would without the implementation of Alternative D. Children may also have an increased risk of heart attacks and death.

Children in Inglewood Unified School District schools may have permanent learning disabilities that limit their career choices and quality of life. Furthermore, they may have shorter lifespans and worse general physical health than other children at other non-impact schools. Inglewood Unified School District students may have lifelong psychological weaknesses that would affect every aspect of their lives.

These adverse health impacts are real. These are the impacts that will disproportionately and significantly affect minority and low income communities.

3. The SEIS/EIR Violates CEQA by Failing to Consider Alternatives that Equitably Distributes Burden Among Populations.

Because of the significant and unmitigatable impact of all of the proposed alternatives, including Alternative D, on minority and low impact communities, other alternatives must be explored.

California *Public Resources Code* § 21002 states, in pertinent part:

“The Legislature finds and declares that it is the policy of the state that public agencies should not approve projects as proposed if there are feasible alternatives or feasible mitigation measures available which would substantially lessen the significant environmental effects of such projects, and that the procedures required by this division are intended to assist public agencies in systematically identifying both the significant effects of proposed projects and the feasible alternatives or feasible mitigation measures which will avoid or substantially lessen such significant effects.”

California law requires the SEIS/EIR to consider feasible alternatives that would substantially lessen the disproportionate and significant environmental effects of the project on minority and low-income communities. LAWA failed to do so.

4. The SEIS/EIR Violates CEQA By Failing to Provide Mitigation Measures for the Significant Environmental Justice Impacts.

The SEIS/EIR is required to mitigate the environmental justice burden imposed by Alternative D to the extent feasible. (California *Public Resources Code* §§ 21002, 21002.1.) The SEIS/EIR, however, fails to describe any mitigation measures to alleviate its impacts on schools. Instead, it proclaims that it will *only* provide mitigation measures in those schools not deemed to be Title 21 compliant. (See *Environmental Justice*, Section 4.4.3.5.1.2, p. 4-329; *Supplemental Aircraft Noise Technical Report*, Section 6.2.3, p. 154.) This rationale is flawed for two reasons: (1) it over-estimates the effect of the Settlement Agreement (See Part Two *infra*); and (2) it fails to address the independent obligations of CEQA.

Feasible mitigation programs exist that would address the noise issues in minority and low income schools. Sound insulation can alleviate noise impacts inside classrooms. To the extent that the significant noise impacts in Inglewood Unified School District schools are unmitigatable, the SEIS/EIR should address the option of relocating those schools.

The same mitigation analysis must be conducted for air quality and other significant impacts of the proposed project upon minority and low-income populations.

To the extent feasible, LAWA is obligated to mitigate its impacts on the Inglewood Unified School District. (14 *California Code of Regulations* § 15126.4.) The SEIS/EIR fails to do so. The failure to include such mitigation measures in the body of the SEIS/EIR violates CEQA. (*Id.*) Accordingly, this SEIS/EIR is fatally inadequate and must, before further action is taken, be revised to comply with CEQA.

PART TWO

THE SEIS/EIR IMPROPERLY RELIES UPON AND OVER ESTIMATES THE EFFECT OF THE SETTLEMENT AGREEMENT

The Original EIS/EIR states in one volume:

“In the mid-1970’s, the City of Los Angeles ... [settled] a noise lawsuit. Under the terms of the settlements, each school in the public ... systems that had participated in the lawsuit agreed to allow an aviation easement, deeming the school to be compatible with the airport under Title 21.” (EIS/EIR, *Land Use*, Section 4.2, pp. 4-95, 4-96.)

In a separate volume, the Original EIS/EIR states:

“As presented in Technical Report 1, *Land Use*, four public schools would be exposed to significantly high levels of noise by 2015 within the City of Inglewood. For those impacted schools not already considered compatible pursuant to California Code of Regulations, Title 21, mitigation in the form of sound insulation or acquisition and relocation would be provided.” (Original EIS/EIR, *Schools Technical Report*, Section 17, p. 11.)

“As presented in Technical Report 1, *Land Use*, eight public schools would be exposed to significantly high levels of noise by 2015 within the Inglewood Unified School District and Lennox Elementary School District. For those impacted schools not already considered compatible pursuant to California Code of Regulations, Title 21, mitigation in the form of sound insulation or acquisition and relocation would be provided.” (Original EIS/EIR, *Schools Technical Report*, Section 17, p. 15.)

The SEIS/EIR picks up on these points when discussing mitigation of noise impacts on schools. (See, for example, *Environmental Justice*, Section 4.4.3.5.1.2, p. 4-329; *Supplemental Aircraft Noise Technical Report*, Section 6.2.3, p. 154.)

Thus, the SEIS/EIR both addresses and dismisses further consideration of the impacts upon Inglewood Unified School District schools solely based upon the existence of the 1970’s Settlement Agreement. (*Amended Judgment and Final Order in Condemnation*, Original

EIS/EIR Response Exhibit 10; the operative "Judgment and Final Order" is actually entitled Amended Judgment and Final Order in Condemnation, and referred to herein as "Settlement Agreement.") It is apparent LAWA has no intention of providing mitigation in any form to Inglewood Unified School District schools as part of Alternative D. As set forth below, this deficient approach (1) fails to even consider the entirety of the terms of the Settlement Agreement; (2) fails to consider other surcharges which would be caused by an expansion not provided for by the express grant of the avigation easement in the Settlement Agreement; and (3) inappropriately avoids and dismisses a proper CEQA analysis.

1. The SEIS/EIR Fails to Consider All Possible Surcharges on the Avigation Easements.

As with the Original EIS/EIR (Original EIS/EIR, *Land Use*, Section 4.2, p. 4-95, fn. 72.), when discussing the historically high noise levels affecting the Inglewood Unified School District, the SEIS/EIR refers to and relies solely upon the Settlement Agreement which granted LAWA an avigation easement over Inglewood Unified School District schools. (SEIS/EIR, *Supplemental Aircraft Noise Technical Report*, Section 6.2.3, p. 154.) The SEIS/EIR concludes:

"LAWA has established agreement with most public and a few private schools in the airport environs related to the amount of cumulative noise that may be generated from airport operations over each. Where those cumulative noise levels are exceeded (measured in decibels of CNEL), addition of the facility to the list of sound insulation eligibility may be warranted." (*Id.*)

This conclusion is incomplete and misstates the Settlement Agreement (discussed further in Part II.2 and II.3 *infra*). The Settlement Agreement provides that the purpose of the air easements granted to LAWA are for "noise, vibrations and fumes" over the schools. (Settlement Agreement, page 3, lines 18-21.) The Settlement Agreement further provides:

"Vibration and fume levels are not quantitatively described for the purpose of the distribution of the air easements but it is agreed that those levels of vibration and fumes which accompany the agreed-to CNEL values shall not be a burden of the easements." (Settlement Agreement, page 11, lines 1-5.)

In other words, LAWA may only contend that the avigation easement is not surcharged if "levels" of vibration and noise are the same as in 1970. What the Settlement Agreement does not discuss, does not preclude, and leaves open is whether a surcharge may occur when the *frequency* of vibrations and fumes is increased from the frequency of vibrations and fumes occurring in 1970.

Paragraphs 4.a and 7 of the Settlement Agreement make clear it was the intent of the parties not to further burden the avigation easements by an increase or "deviation" in frequency

of flight operations over Inglewood Unified School District schools. Rather such deviations were only permitted if "temporary and not permanent." (Settlement Agreement, page 13, line 14.)

2. The Impacts of the Alternate D Will Constitute a Surcharge on the Avigation Easements.

Under California law, the extent of an easement is determined by the terms of its grant. (California Civil Code § 806.) As stated by the California Supreme Court, an owner of an easement may not increase the use of the easement in any manner that imposes a new or greater burden on the servient tenement without the consent of the servient owner. (*Colegrove W. Co. v. City of Hollywood* (1907) 151 Cal. 425, 429.) Further, "...it is well settled that 'both parties have the right to insist that so long as the easement is enjoyed it shall remain substantially the same as it was at the time the right accrued, entirely regardless of the question as to the relative benefit and damage that would ensue to the parties by reason of a change in the mode and manner of its enjoyment. [Citation omitted.]'" (*Whalen v. Ruiz* (1953) 40 Cal.2d 294, 302.)

In fact, "California courts have set their faces firmly against ... increases in the burden upon the servient tenement." (*Wall v. Rudolph* (1961) 198 Cal.App.2d 684, 694.) Accordingly, "[t]he requirement that the easement involve only a *limited* use or enjoyment of the servient land is a corollary of the nonpossessory character of the interest. If a conveyance purported to transfer to A an *unlimited* use or enjoyment of [a parcel of land], it would be in effect a conveyance of ownership to A [of the parcel of land], not of an easement." (*Id.*, at p. 697; emphasis in original.)

The avigation easement granted by the Inglewood Unified School District to LAWA was based upon criteria which have been far exceeded. For example, the number of take-offs and landings identified in Exhibit F in 1970 (used as two of the three elements to establish the CNEL contours) has dramatically increased as of 2003. In 1970, the total of take-offs and landing events per day was 1,061. (Settlement Agreement, Exhibit F, Figures 6, 7.) The total number of take-offs and landing events per day in 2003 is over 1,700, an increase in flight frequency of over 62%. (Los Angeles World Airports, *Traffic Comparison*, May 28, 2003.) This will increase even further to 2,148 under Alternative D, that is, over 100% more than anticipated by the avigation easement. (SEIS/EIR, *Executive Summary*, Table ES-1.)

Moreover, the avigation easement anticipated an *increase* in aircraft operations at LAX up to 40,000,000 passengers annually. (Settlement Agreement, Exhibit F, paragraph B.) LAX is currently operating at over 51,000,000 passengers annually. (Los Angeles World Airports, *Traffic Comparison*, May 28, 2003.) Alternative D predicts an increase in aircraft operations to accommodate at least 78,900,000 passengers annually, once again, almost 100% more than anticipated by the Settlement Agreement. (SEIS/EIR, *Executive Summary*, Table ES-1.) In addition, the amount and frequency of airplane traffic will also necessarily increase under Alternative D to accommodate the predicted increase in cargo tons per year by 50% over today's traffic alone. (*Id.*)

Perhaps most significant, however, is the *decrease in altitude* of air traffic over Inglewood Unified School District schools proposed by Alternative D due to the eastward extension of runway 24L and its direct impact on “levels” of noise, vibration and fumes. (See, SEIS/EIR, *Noise*, Sections 4.1.6.1.5.3 and 4.1.6.1.5.4.2, pp. 4-64 and 4-66, respectively.)

Thus, the increase in *frequency* of air traffic through the avigation easement proposed by Alternative D will constitute a material surcharge upon the easement. This increased frequency results in an increase in not only the number of noise events, but in the number of *vibration* and *fume events* as well.

This burden on the easement will, at the very least, require the Inglewood Unified School District’s consent, and realistically also require further mitigation in the form of additional sound attenuation measures at each of the affected school sites.

Therefore, the SEIS/EIR must further consider, and LAWA must mitigate, the impact upon the existing or future incompatible land use resulting from implementation of Alternative D, as the Judgment and Final Order will not, as suggested, conclusively control the question given the anticipated substantial surcharge upon the avigation easement and resulting burden to the servient tenement, Inglewood Unified School District schools.

3. The Existence of the Settlement Agreement is Irrelevant to Whether LAWA Must Comply With CEQA.

The existence of an avigation easement alone does not render a school “Compatible” under Title 21. Throughout the SEIS/EIR, LAWA implies that those schools which entered into avigation easements with LAWA are automatically deemed “compatible” uses, and therefore do not require mitigation. The regulatory definitions of “compatible” and “incompatible” uses do not support this contention.

The definition of incompatible land uses includes:

“[P]ublic and private schools of standard construction for which an avigation easement for noise has not been acquired by the airport proprietor *or* that do not have adequate acoustic performance to ensure an interior CNEL of 45 dB or less in all classrooms due to aircraft noise.” (Emphasis added.) (21 *California Code of Regulations* 5014(b).)

The definition stated in the disjunctive is not of “compatible” land uses, but of “incompatible” land uses. Thus, public schools with an interior CNEL of 45 dB are plainly “incompatible” land uses, with or without an avigation easement. The accepted rules of statutory construction simply do not allow any other interpretation or extrapolation to be made by LAWA.

Under the basic tenets of statutory construction, courts will,

“ascertain the intent of the drafters so as to effectuate the purpose of the law [by] . . . first examin[ing] the words themselves, giving

them their usual and ordinary meaning and construing them in context. When statutory language is clear and unambiguous, 'there is no need for construction and courts should not indulge in it.' [Citations omitted.]" (*Esberg v. Union Oil Co.*(2002) Cal.4th 262, 268.)

In this case, the plain meaning of the regulation does not present any ambiguity. The use of the word "or" in a regulation indicates an intention to use it disjunctively so as to designate alternative or separate categories. (*Piet v. U.S.* (1959) 176 F. Supp. 576, 583.)

Therefore, those schools that do not have adequate sound insulation to ensure an interior CNEL of 45 dB or less, are incompatible uses for purposes of Title 21 and *are entitled* to mitigation irrespective of whether LAWA holds aviation easements for those schools.

Even if LAWA successfully maintains Alternative D is not a surcharge on the aviation easement granted by Inglewood Unified School District, and, despite the foregoing, is nonetheless "compliant" with Title 21, LAWA must still identify the need for and then provide for the implementation of mitigation measures. Under California law:

"Any one may waive the advantage of a law intended solely for his benefit. But a law established for a public reason cannot be contravened by private agreement." (*California Civil Code* § 3513.)

The California Environmental Quality Act ("CEQA") is a state environmental law applicable to public agency decisions to authorize projects that could have an adverse impact on the environment. The purpose of the CEQA Environmental Impact Report requirement is to provide the information needed to make informed decisions in the selection and authorization of projects. (*California Public Resources Code* §§ 21001(g), 21002, 21061; 14 *California Code of Regulations* § 15121.) Without question, CEQA and its requirements are "established for a public reason." Therefore, under both sound principles of law as well as fundamental considerations of fairness and justice, the existence of the aviation easement (a private agreement between two public agencies) cannot "waive" the requirement of mitigation of the significant impacts upon students and teachers associated with Alternative D.

Thus, appropriate project alternatives, significant impacts and related mitigation measures must be analyzed in the SEIS/EIR. (*California Public Resources Code* §§ 21002.1, 21100.) In this instance, the SEIS/EIR must identify measures that would mitigate the impacts of Alternative D on Inglewood Unified School District in general and impacted school facilities in particular. (*Id.*) Without this analysis, the selection process is flawed and an informed decision cannot be made.

The Settlement Agreement between the City of Los Angeles and various school districts does not affect this state mandated analysis. The SEIS/EIR claims that the Settlement Agreement operates to mitigate significant impacts upon schools and students. (*Environmental Justice*, Section 4.4.3.5.1.2, p. 4-329; *Supplemental Aircraft Noise Technical Report*, Section 6.2.3, p. 154; See also, EIS/EIR, *Land Use*, Section 4.2.) This claim is in direct contradiction to

the requirements of CEQA (14 California Code of Regulations § 15126.4) and Civil Code §3513.

CEQA requires LAWA to conduct and publicly disclose its analysis of impacts upon affected schools and of measures that can mitigate those impacts, if any. (*Id.*) Thus, the SEIS/EIR must be revised to conduct a thorough analysis of impacts upon schools and of measures that can be taken to mitigate those impacts. (*Id.*)

PART THREE

THE NOISE ANALYSIS OF THE SEIS/EIR IS INADEQUATE²

1. The SEIS/EIR Under-predicts Noise Impacts to Inglewood Unified School District Facilities by Omission.

There appears to be no specific mention of the following Inglewood Unified School District educational facilities within the SEIS/EIR:

- Inglewood Adult School, located at 106 East Manchester Blvd. Given its proximity to Inglewood High School (which is identified as a noise impacted school, within the SEIS/EIR) this lack of reference to Inglewood Adult School appears to be an oversight.
- City Honors School, which is located on the Morningside High School Campus.
- The following schools are not mentioned., This may be because they are not impacted, but the Inglewood Unified School District would request some acknowledgement of the existence of these schools within the Final EIS/EIR to provide reassurance that these schools have not merely been overlooked in the analysis:

Bennett/Kew Elementary School, located at 1170 South Cherry Avenue.

La Tijera Elementary School, located at 1415 North Tijera Boulevard.

Parent Elementary School, located at 5354 West 64th Street.

²For the purpose of these comments, the use of the terms "Decibel", "dB" and "dBA" are all intended to mean A-weighted decibels.

2. The SEIS/EIR Under-Predicts Noise Impacts on Inglewood Unified School District Facilities by Relying on Noise Modeling Results Which Are Acknowledged Within the Report to under-Predict Actual Aircraft Noise Levels.

As discussed in the *Supplemental Aircraft Noise Technical Report* (page 15) the INM used for all noise predictions in the SEIS/EIR under-predicts aircraft noise in comparison to real measured noise levels. The study's under-prediction of noise levels is likely to lead to an under-prediction of the number of schools at which the 2015 aircraft noise levels exceed certain noise thresholds of significance. The Inglewood Unified School District recommends that the Final EIS/EIR include detailed analysis of the likely real noise impact upon Inglewood Unified School District schools.

3. The "Single Event" Noise Analysis Presented in the SEIS/EIR is Incomplete.

The Inglewood Unified School District's comments on the Original EIS/EIR pointed out potential disruption to speech communication within classrooms associated with "single events," i.e., the noise associated with individual aircraft flyovers. The Inglewood Unified School District is pleased to see that single events are now considered within the SEIS/EIR. The District remains concerned, however, that the issue of the applicable threshold(s) of significance has not been resolved within the SEIS/EIR.

Mitigation measure MM-LU-4, which incorporates specific noise mitigation measures for schools, is "subject to modification" based upon the results of further study. Details of the proposed 'further study' are not, however, provided for our comment.

4. The Limited 'Single Event' Noise Analysis Presented in the SEIS/EIR Substantially Under-predicts Impacts to Inglewood Unified School District Facilities in a Number of Ways.

a. The indoor classroom L_{max} thresholds are set too high.

The *Supplemental Aircraft Noise Technical Report* proposes a 55 dBA L_{max} threshold of significance for teaching classes. According to Page 149 of this report, this threshold was derived from Table 3.3 of a 1992 FICON publication, using a speaker-to-listener distance of 20 feet and assuming a raised voice level. Reference to the FICON 1992 publication shows that the table in question was reproduced from the 1973 EPA publication, "Public Health and Welfare Criteria for Noise," ("EPA Report") as Figure 6.1 of the EPA Report.

The EPA Report qualifies the data in a number of important ways. The qualifications include the following:

- Figure 6.1 published by EPA in 1973 was for an outdoor noise environment. Page 6-7 of the EPA Report states that the data "is not valid to assess the intrusion of the outdoor levels on the reception of speech indoors because of the reverberant build up of sound by reflections from the walls of the room. . .

The data in the pertinent literature suggests that, for most instances, a reasonable value for the design of rooms where oral communication is important is somewhere in the range 40-45 dBA.”

- Page 6-7 of the EPA Report goes on to state, “Lower noise levels would be required if the talker has imprecise speech (poor articulation) or if the speaker and listener speak different dialects.” Considering the fact that (1) the speaker in the classroom is occasionally the student, and (2) the student’s first language is often not the same as that of the teacher, these qualifications are certainly applicable in Inglewood Unified School District schools.
- Page 6-7 of the EPA Report also states that the data in its Figure 6.1 represents conditions for young adults and that “adequate speech communication with children requires lower noise levels than are required for adults”. This qualification also applies to most Inglewood Unified School District schools.
- Pages 6-7 to 6-8 of the EPA Report also state, “Persons with hearing losses require more favorable speech-to-noise ratios than do those with normal hearing.” Given that all pupils will not all have perfect hearing at all times, due in great part, but not exclusively, to frequent childhood ear infections, this qualification is also pertinent.

The EPA qualifications of the data were not contemplated in the SEIS/EIR analysis. Appropriate consideration of these qualifications would result in a lower threshold for the application in question.

On the above basis, the Inglewood Unified School District believes the 55 dBA L_{\max} indoor criterion used in the SEIS/EIR to be incorrectly derived. A lower criteria based upon consideration of all relevant factors, including: talker-to-listener distances greater than 20 feet, noise effects in indoor environments, the need for a higher signal-to-noise ratio for children, children’s propensity to temporary hearing loss, and children with limited English proficiency should be utilized by LAWA.

b. Classroom interior noise levels based upon assumed 29 dBA out-to-in aircraft noise reduction do not adequately protect a large enough proportion of classroom users in the Inglewood Unified School District.

According to the *Supplemental Aircraft Noise Technical Report*, the 29 dBA out-to-in noise reduction for aircraft noise intrusion to classrooms is the average result of sample measurements conducted at “several schools” by LAWA. (p. 149.) Insufficient details were provided in the SEIS/EIR to assess whether the sampling was applicable to Inglewood Unified School District classrooms. Furthermore, since the 29 dBA is an average result, several classrooms in the study must have lower sound attenuation levels. It is therefore likely that sound insulation for some Inglewood Unified School District classrooms would be lower than 29 dBA.

Deriving an indoor noise impact threshold using the 29 dBA average would not adequately protect the occupants of those classrooms with worse than average sound isolation. For example, as is common in Southern California, the Inglewood Unified School District utilizes 'bungalow'/'modular' type classrooms. These would not generally be expected to provide such a high level of out-to-in noise reduction for aircraft noise. The noise threshold for mitigation should be designed to protect actually impacted classrooms, not just the 'average' case.

- c. **The SEIS/EIR's proposed 84 dBA L_{max} outdoor single event noise threshold is too high to assess single event noise impact upon classrooms, leading to a severe under-reporting of existing and future noise impacts.**

The World Health Organization ("WHO") states that for speech to be intelligible when listening to complicated messages, such as in schools, interfering noise should not exceed 35 dBA. (World Health Organization, *Guidelines, supra.*) Assuming the classrooms in question operate with closed windows and doors (which would assume the existence of air-conditioning in the classrooms) and have been provided with sound attenuation to achieve a minimum noise level reduction of 25 dB (as required under the Land Use Compatibility Guidelines of the Federal Aviation Regulations for schools exposed to aircraft noise in the CNEL 65 to 70 range), this would suggest that occurrence of outdoor noise levels exceeding 60 dBA, which is much lower than the 84 dBA threshold, would result in speech interference within classrooms.

Even using the upper limit of the EPA's suggested range (see item 4 a., above) of 45 dBA as being a threshold above which interference with typical speech becomes noticeable indoors, and again assuming 25 dBA out-to-in sound insulation, such a conservative analysis would suggest speech disturbance would be noticeable when outdoor noise levels exceed 70 dBA. Again this is a much lower threshold than 84 dBA.

Table S17 of the *Supplemental Aircraft Noise Technical Report* presents results for time above 75 dBA outdoors. Reviewing the range of thresholds for speech interference discussed above, it is highly likely that aircraft noise levels exceeding 75 dBA at a school result in speech interference within classrooms. (As discussed above, the appropriate threshold is probably lower than 75 dBA.) Table 1 below, presents "time above" data in minutes, projected for the year 2015 unless otherwise indicated, for Inglewood Unified School District schools extracted from Table S17 of the *Supplemental Aircraft Noise Technical Report*.

Table 1 - Aircraft Noise Time above 75 dBA in Minutes, for the year 2015 unless otherwise stated.

School	1996	No Project	Alt. A	Alt. B	Alt. C	Alt. D
Beulah Payne Elementary School - PBS017	3.6	9.0	13.8	2.1	5.0	12.1

Clyde Woodworth Elementary School - PBS026	9.4	9.8	12.6	19.3	10.1	19.2
Crozier Middle School - PBS028	0.2	0.3	4.9	0.5	0.4	0.2
Hillcrest High School - PBS047	31.5	39.8	45.9	47.6	43.5	37.3
Claude Hudnall Elementary School - PBS048	1.9	1.4	4.0	6.7	6.8	3.1
Inglewood High School - PBS050	7.6	11.1	16.1	30.3	32.7	13.6
Kelso Elementary School - PBS059	32.5	42.6	44.8	43.0	38.3	38.3
Oak Street Elementary School - PBS105	42.1	53.6	63.9	51.0	50.4	48.3
Warren Lane Elementary School - PBS117	0.2	0.9	0.7	1.1	1.2	0.9
Worthington Elementary School - PBS127	0.1	0.1	0.7	1.3	0.1	0.1
Morningside High School - PBS140	12.6	12.8	19.7	18.6	13.8	13.7
Albert Monroe Middle School - PBS201	3.9	4.6	6.6	23.6	4.3	4.1

The results presented in Table 1 suggest that the cumulative duration of speech interference in classrooms per day for all of the above Inglewood Unified School District schools will increase from "1996 baseline" levels under nearly every project alternative scenario. Given the amount of speech disturbance at 1996 levels indicated by the conservative analysis presented above, any further increase in cumulative duration of speech disturbance is of serious and immediate concern. The *Supplemental Aircraft Noise Technical Report's* reliance on analysis using a time above 84 dBA outdoor noise level clearly understates the existing and future aircraft noise disturbance at Inglewood Unified School District facilities.

When speech interference occurs in the classroom, students suffer a loss of learning time. Other possible outcomes include students failing to understand important information from the teacher, loss of concentration during study, or interference with standardized testing. (See Part One, Section 2b., *supra*.) The predicted increase in the duration of speech interference in Inglewood Unified School District classrooms gives rise to serious noise impacts that do not receive adequate attention in the SEIS/EIR.

d. The main body of the SEIS/EIR should consider significantly increased cumulative duration to excessive noise levels as a significant noise impact.

The *Supplemental Aircraft Noise Technical Report* introduces three thresholds of significance for single event impacts upon classrooms (55 dBA L_{max} , 65 dBA L_{max} and 35 dBA L_{eq} (1 hour)). It states, "Each school listed on the tables may, for CEQA purposes, be considered single event impacted if its noise level exceeds any of the three thresholds of significance . . ."

(SEIS/EIR, *Supplemental Aircraft Noise Technical Report*, Section 6.2.2, p. 150.) The main body of the SEIS/EIR, however, appears to only consider *new exposure* to levels above these thresholds (as opposed to all levels in excess of these thresholds) as the threshold of significance. This is in clear contrast to the pronouncements in the *Supplemental Aircraft Noise Technical Report*. No justification has been provided in the SEIS/EIR for its failure to acknowledge these impacts.

This can be illustrated by the example of Oak Street Elementary School. According to the *Supplemental Aircraft Noise Technical Report*, the classrooms at this school are exposed to instantaneous indoor noise levels exceeding 55 dBA for a cumulative duration of 2.7 minutes per day (comprising of 45.9 individual noisy events) based upon the 1996 baseline. Under Alternative D, in 2015, this cumulative duration would increase to 8.6 minutes per day (comprising of 98.3 individual noisy events). This is a more than 300% increase in cumulative daily exposure to classroom noise levels above 55 dBA, yet the main body of the SEIS/EIR, which uses *new exposure* to any event louder than 55 dBA levels as the threshold of impact for single events, fails to acknowledge a noise impact at this school.

The *Supplemental Aircraft Noise Technical Report*, in Table S33, also includes analysis of the increases in the cumulative duration above the threshold of 35 dBA L_{eq} in classrooms. Under Alternative D, the following schools are all predicted to suffer increases to the cumulative duration in 2015 compared to the 1996 baseline:

Kelso Elementary School
Oak Elementary School
Beulah Payne Elementary School
Clyde Woodworth Elementary School
Monroe Middle School
Hillcrest High School
Inglewood High School
Morningside High School

However, since only the latter two schools are *newly exposed* to levels above 35 dBA L_{eq} , an impact has not been declared for the other schools. The somewhat arbitrary nature of the *newly exposed* requirement for a significant impact is illustrated by the fact that Morningside High School is considered as significantly impacted, whereas immediately adjacent schools Clyde Woodworth Elementary School and Monroe Middle School are not.

It should also be noted that all the schools listed above are, according to the SEIS/EIR, already (based upon the 1996 baseline) exposed to noise levels above the 35 dBA L_{eq} threshold for at least 30 minutes per school day. Given the substantial amount of existing speech disturbance, any increase in cumulative duration of speech disturbance is considered troubling and again, use of the *newly exposed* requirement leads to an understatement of the noise impact associated with all of the project alternatives considered.

5. The Project Alternatives Included in the EIS/EIR Do Not Appear to Satisfy CEQA or NEPA Requirements.

According to Title 14 *California Code of Regulations*, Chapter 3, Guidelines for Implementation of CEQA:

“An EIR shall describe a range of reasonable alternatives to the project, or to the location of the project, which would feasibly attain most of the basic objectives of the project but would avoid or substantially lessen any of the significant effects of the project.”
(15 *California Code of Regulations* § 15126.6(a).)

Significant noise impacts are predicted for Inglewood Unified School District schools under each alternative considered, including the “No Action/ No Project” alternative. No alternative has been considered that would avoid or substantially lessen the noise impact upon Inglewood schools as required by CEQA.

According to the Council for Environmental Quality, a NEPA analysis:

“. . . shall inform decision makers and the public of the reasonable alternatives which would avoid or minimize adverse impacts or enhance the quality of the human environment. . . [including]. . . reasonable alternatives not within the jurisdiction of the lead agency.”

In this context, a proper NEPA analysis should include at least one alternative whereby a significant noise impact was avoided in Inglewood schools by diverting the proposed increased heavy jet traffic to other airports.

6. The Analysis of Temporary Aircraft Noise Impacts Is Inadequate.

Table S4.1-5 of the main body of the SEIS/EIR shows that in the year 2008, under Alternative D, Beulah Payne Elementary School will be exposed to higher daily aircraft noise levels (67.2 dBA, compared to a 1996 baseline level of 58.6 dBA). It appears that there will be elevated aircraft impacts during portions of the construction phase.

This is acknowledged within the *Supplemental Aircraft Noise Technical Report* (see p. 26, for example), but the main body of the SEIS/EIR does not appear to provide any analysis of temporary aircraft noise impact on the other Inglewood Unified School District schools, a discussion of how long they might last, or a recommendation for any mitigation measures. As with all significant adverse impacts, these construction impacts must be described and analyzed and mitigation measures presented.

7. Inadequate/Mislabeled Data in Supplemental Aircraft Noise Technical Report.

The *Supplemental Aircraft Noise Technical Report*, which presents the specific noise calculation results relevant to Inglewood Unified School District schools, provides data labeled as 'DNL' in Table S14. It is unclear whether this data is actually CNEL data that has been mislabeled. Since the project thresholds of significance are set in terms of CNEL rather than DNL, providing DNL data prevents the reader from looking at predicted CNEL impacts on specific Inglewood Unified School District schools.

8. Specific Noise Mitigation Measures for Inglewood Unified School District Facilities Are Not Clearly Stated in the SEIS/EIR.

According to Title 14 *California Code of Regulations*, Chapter 3, Guidelines for Implementation of CEQA:

“An EIR shall describe feasible measures which could minimize significant adverse impacts...the discussion of mitigation measures shall distinguish between the measures which are proposed by project proponents to be included in the project and other measures proposed by the lead, responsible or trustee agency or other persons which are not included but the lead agency determines could reasonably be expected to reduce adverse impacts if required as conditions of approving the project. This discussion shall identify mitigation measures for each significant environmental effect identified in the EIR.” (14 *California Code of Regulations* § 15126.4.)

Mitigation measure MM-LU-4, which incorporates noise mitigation measures for schools, is “subject to modification” based upon the results of further study. Details of the proposed ‘further study’ are not, however, provided for review. The proposed noise mitigation measures (further study excluded, because study alone will not do anything to mitigate the predicted noise impact) are not therefore clearly stated in the report.

a. The SEIS/EIR’s analysis of the health effects of noise on students is flawed.

i. The SEIS/EIR improperly relies on a flawed FICON document.

The SEIS/EIR relies heavily on noise level standards from a document prepared by the Federal Interagency Committee on Noise (“FICON”) entitled “Federal Agency Review of Selected Airport Noise Analysis Issues.” This document is misrepresented in the report and should not be relied upon. The misrepresentation is to describe this document as a “study detailing the degree of speech understanding at various noise levels....” (SEIS/EIR, *Noise*, Section 4.1.2.1.2, p. 4-12.)

First, FICON is an interagency task force consisting of representatives from various government agencies. It does not consist of experts on noise or noise impacts on children who have appropriate scientific training and experience to critically evaluate and summarize a scientific body of literature.

Second, there are many individuals on FICON with clear conflicts of interest in assessing the scientific literature. The majority of FICON representatives work for federal agencies that are major producers of noise (e.g., Federal Aviation Administration ("FAA"), the U. S. military, National Aeronautics and Space Administration ("NASA").

Third, the entire FICON document devotes five pages to the topic of speech communication. No scientific analysis could "detail the degree of speech understanding" in such a limited manner. The uncritical acceptance of the FICON document reflects a serious lack of understanding and knowledge of the scientific literature on the effects of noise on children's learning and speech perception.

Fourth, some important data the FICON document relies upon are outdated and in some cases inaccurate. For example, Table 3.3 in the FICON document which is reprinted from a 30 year old Environmental Protection Agency ("EPA") document ("EPA Report") is widely rejected in the scientific community in its applicability to children's learning. Data from adults listening to a trained speaker conversing in the outdoors were used to develop this Table. It has long been known that children need a larger signal to noise ratio to comprehend speech than an adult, and noise effects in interior environments must take into account sound intensity and reverberation time (time for sound to decay). (American National Standards Institute, "Acoustical performance criteria design requirements and guidelines for schools.", ANSI S12.60-2002, Exhibit 19; World Health Organization, *Environmental Health Information, Guidelines for Community Noise*, 2000; Nelson, P. & Soli, S., "Acoustical barriers to learning: Children at risk in every classroom." *Language, Speech, and Hearing Services*, 31: 356-361, 2000; Picard, M., & Bradley, J.S., "Revisiting speech interference in classrooms." *Audiology*, 40: 221-244, 2001) The FICON document and the SEIS/EIR which relies primarily on the FICON document is replete with errors of this sort.

Fifth, the FICON document omits abundant research on airport noise and deficits in reading acquisition. More than 20 studies around the world (Evans, G.W. & Lepore, S.J., "Nonauditory effects of noise on children." *Children's Environments*, 10: 31-51, 1993; Kryter, K.D., "The handbook of hearing and the effects of noise." San Diego, Academic Press, 1994, Exhibit 20; World Health Organization, *Environmental Health Information, Guidelines for Community Noise*, 2001) including a dose response relationship (Green, K., Pasternack, B. & Shore, R., "Effects of aircraft noise on reading ability of school age children." *Archives of Environmental Health*, 37: 24-31, 1982, Exhibit 21) interventions to reduce noise (Bronzaft, A., "The effect of a noise abatement program on reading ability." *Journal of Environmental Psychology*, 1: 215-222, 1981) and most convincingly, a prospective, longitudinal study (i.e. the same children are compared before and after the opening of a major new airport) (Hygge, S., Evans, G.W., & Bullinger, M., "A prospective study of some effects of aircraft noise on cognitive performance in school children." *Psychological Science*, 13: 469-474, 2002, Exhibit 22), show significant deficits in reading from transportation related noise exposure.

ii. The SEIS/EIR Ignores the Scientifically Confirmed and Well Established Link Between Noise Exposure and Children's Learning.

The SEIS/EIR relies heavily on FICON's flawed logic in developing its basic arguments. The SEIS/EIR states that "there is no reliable statistical relationship between the amount of aircraft noise exposure present and the degree of learning difficulty experienced by children at affected schools. . ." (SEIS/EIR, *Noise*, Section 4.1.2.1.2, p. 4-11.) First unless the SEIS/EIR consulting team includes individuals trained in statistics and research design methodology, this claim is suspect prima facie. Second, because there is very little data (consisting of one airport study (Green, K., Pasternack, B. & Shore, R. "Effects of aircraft noise on reading ability of school age children." *supra*) and one road traffic study (Lukas, J.S., DuPree, R.B. and Swing, J.W. *Effects Of Noise On Academic Achievement And Classroom Behavior, supra.*) to be exact, not zero as stated by FICON and uncritically repeated in the SEIS/EIR) showing a dose-response relationship between noise levels and learning deficits, the report presumes therefore there is no evidence to support a link between noise exposure and learning difficulties. This is patently false.

There are multiple sources of evidence to demonstrate a relationship between airport noise exposure and significant deficits in children's learning. Many studies show that aircraft noise is significantly related to deficits in reading acquisition (see reviews in Evans, G.W. & Lepore, S.J., "Nonauditory effects of noise on children." *Children's Environments*, 10: 31-51, 1993, Exhibit 23; Kryter, K.D. "The handbook of hearing and the effects of noise." *supra*; World Health Organization, *Guidelines*, 2001, *supra.*). Not one of these studies is cited in the FICON document or the SEIS/EIR. This is a glaring omission in an SEIS/EIR that is mandated by state and federal law to consider potential health and welfare costs and benefits of a proposed project. The focus on speech and communication should be at least matched by an analysis of the noise and reading acquisition literature.

In contrast to the FICON document, the SEIS/EIR briefly notes a more recent American National Standards Institute ("ANSI") classroom standard criterion established in "Acoustical Performance Criteria, Design Requirements, and Guidelines for Schools" *supra* (hereinafter referred to as "ANSI Report"). This document recommends lower levels of acceptable noise intensity in classrooms than FICON. The SEIS/EIR omits discussion of the World Health Organization ("WHO") noise criterion document, "Adverse Health Effects of Noise," Section 3, April 2001, (hereinafter referred to as the "WHO Report"), which predates the ANSI study by a few years. The WHO and ANSI standards converge on 35 dBA for an interior noise standard for elementary school classrooms. What is particularly important to understand is that unlike the FICON document, the ANSI and WHO reports were developed by scientists knowledgeable about noise and its human impacts. These reports are much more detailed and provide a thorough discussion and analysis of the evidence. In the case of the WHO Report, it represents a consensus statement of leading noise researchers in the world on the current level of knowledge about noise and its impacts and provides recommendations of acceptable noise standards to protect the public. Unlike the FICON document, the WHO and ANSI reports were also widely distributed to scientists in draft form for critical feedback, and then went through multiple iterations of revisions. There was substantially scientific peer review of the WHO and ANSI reports. This did not occur for the FICON document.

iii. The SEIS/EIR Entirely Neglects the Substantiated Link Between Noise and Other Adverse Learning and Health Effects on Children.

The SEIS/EIR also does not consider evidence of other adverse learning and health effects on children chronically exposed to aircraft noise. These are widely available in the scientific literature. Children chronically exposed to noise suffer from motivational deficits. They persist less in achievement related contexts. Both laboratory (Glass, D.C. "Behavior patterns, stress, and coronary heart disease." Hillsdale, NJ: Erlbaum, 1977,) and field studies of noise (Bullinger, M., Hygge, S., Evans, G.W., Meis, M. and von Mackensen, S., "The Psychological Cost of Aircraft Noise for Children," *supra.*; Evans, G.W., Hygge, S. & Bullinger, M., "Chronic noise and psychological stress." *Psychological Science*, 6: 333-338, 1995, Exhibit 24) show that children are less likely to continue efforts in problem solving if they have been exposed to uncontrollable noise. These motivational deficiencies are believed to be caused by the uncontrollable nature of ambient noise exposure.

Constant exposure to a noxious, uncontrollable stressor like noise produces learned helplessness (Peterson, C., Maier, S. & Seligman, M.E.P., "Learned helplessness." NY: Oxford Press, 1993). Individuals learn that regardless of their efforts to cope with an adverse environmental condition, they cannot do anything about it. The outcomes of their behaviors are noncontingent on their behaviors. It is worth noting that the most common way learned helplessness is produced in human laboratory studies, is to expose individuals to uncontrollable noise. There is very strong evidence from human experiments that exposure to uncontrollable noise can produce significant decrements in task persistence. Field studies with children indicate parallel trends from chronic exposure to aircraft noise (See for reviews Cohen, S., "Aftereffects of stress on human performance and social behavior: A review of research and theory." *Psychological Bulletin*, 88: 82-108, 1980, Exhibit 25; Evans, G.W., "Environmental stress and health." In A. Baum, T. Revenson & J.E. Singer (Eds.), *Handbook of Health Psychology*. Mahwah, NJ: Erlbaum, 2001, Exhibit 26; Glass, D.C., & Singer, J.E., "Urban stress: experiments on noise and social stressors." NY: Academic Press, 1972; Peterson, C., Maier, S. & Seligman, M.E.P. "Learned helplessness.," *supra.*)

Additionally, there are several studies documenting links between chronic noise exposure in children and elevated blood pressure. There are no dose response data, but several studies with different research designs (cross-sectional, intervention, longitudinal) show that airport noise exposure is associated with higher blood pressure in children. (See for reviews Evans, G.W. "Environmental stress and health." *supra.*; Ising, H. Babisch, W., & Kruppa, B., "Acute and chronic noise stress as cardiovascular risk factors." *Noise and Health*, 4: 37-48, 1999; World Health Organization, *Environmental Health Information, Guidelines for Community Noise*, 2001, *supra.*) A smaller number of studies also find evidence of elevated stress hormones from exposure to airport noise (Evans, G.W., Bullinger, M. and Hygge, S., "Chronic Noise Exposure and Physiological Response: A Prospective Study of Children Living Under Environmental Stress." *Psychological Science*, Vol.9, No.1, January 1998, Exhibit 27; Ising, H., et al. "Acute and chronic noise stress as cardiovascular risk factors.," *supra.*) It is well known that children with higher blood pressure will tend to have higher blood pressure as adults.

b. The SEIS/EIR's Proposed Noise Study is Inadequate.

i. LAWA May Not Postpone Its Proposed Noise Study Absent a Commitment by LAWA to Mitigate.

The California Environmental Quality Act requires that, whenever feasible, all impacts must be mitigated for any project that is carried out by or approved by a public agency. California *Public Resources Code* §§ 21002, 21002.1(b). Thus, significant effects on the environment must be either eliminated or *substantially* minimized where feasible. (*Berkeley Keep Jets Over the Bay Committee v. Board of Port Commissioners* (2001) 91 Cal.App.4th 1344, 1355.)

According to the SEIS/EIR, LAWA will initiate a study of the relationship between aircraft noise levels and the ability of children to learn. (SEIS/EIR, *Land Use*, Section 4.2, p. 4-210.) Based upon this study, LAWA will set a new threshold of significance for classroom disruption. (*Id.*)

Nonetheless, the SEIS/EIR is vague, inconclusive and inconsistent with respect to actual mitigation. The SEIS/EIR makes no clear statement or commitment to mitigate the impacts even after establishing the new threshold of significance discussed above.

According to California law, LAWA must make a binding "commitment" to achieve a desired level of mitigation. (*Sacramento Old City Association v. City Council of Sacramento* (1991) 229 Cal.App.3d 1011, 1028.) One manner in doing so is to effectuate "specific performance criteria articulated at the time of project approval." (*Id.* at 1029.) Without either a binding commitment or a performance standard, the CEQA analysis is flawed.

For example, the SEIS/EIR states that "any schools found to exceed a newly established threshold of significance for classroom disruption shall be incorporated into the ANMP administered by LAWA." (SEIS/EIR, *Land Use*, Section 4.2, p. 4-210.) According to the SEIS/EIR, the ANMP performance standard is as high as 45 CNEL. (SEIS/EIR, *Land Use*, Section 4.2, p. 4-198.) Since the new threshold of significance will in all likelihood be lower than 45 CNEL, reliance on the ANMP performance standard would render the new threshold immaterial for mitigation purposes.

Also, conflicting language in the SEIS/EIR, creates ambiguity as to whether LAWA will provide substantial mitigation. The SEIS/EIR states that mitigation measures would "mitigate schools that are impacted by significant single event levels through further study of the relationship between the learning and aircraft noise exposure levels, and the subsequent sound insulation of schools where impacts are shown to be significant." (SEIS/EIR, *Noise*, Section 4.1, p. 4-80.) The *Supplemental Aircraft Noise Technical Report*, however, hedges by associating eligibility for mitigation with the CNEL levels in the Settlement Agreement. (Section 6.2.3, p. 154.) Additionally, it states that "the potential for additions to the sound insulation program for schools will be revisited as part of LAWA's continuing environmental management responsibilities." (*Id.*)

The SEIS/EIR does not state whether LAWA will mitigate to levels below significance (i.e. below the new threshold of significance). Nor does the SEIS/EIR provide a "standard of

performance” for noise mitigation. It also does not clarify whether this mitigation will occur in schools it believes are otherwise “compatible” under Title 21. (See, e.g., SEIS/EIR, *Environmental Justice*, Section 4.4.3.5.1.2, p. 4-329.)

Although the SEIS/EIR acknowledges the impact of aircraft noise on children’s learning, it does not commit to mitigation. The SEIS/EIR’s inconclusive approach circumvents the mitigation analysis called for by CEQA.

ii. A Deferred Noise Analysis Is Inappropriate.

Possible impacts must be studied as early as possible to avoid deferment of formulation of mitigation measures. (See, *Sundstrom v. County of Mendocino* (1988) 202 Cal. App. 3d 296, 307.) In general, “an environmental assessment, including a statement of the mitigation measures, may not be deferred until a future study or project.” (*Rio Vista Farm Bureau Center v. County of Solano* (1992) 5 Cal.App.4th 351.)

There is substantial evidence currently before LAWA that significant impacts of aircraft noise on children’s learning will occur. Despite this, LAWA is deferring the assessment of this impact. CEQA requires environmental review at the earliest feasible stage in the planning process. California *Public Resources Code* Section 21003.1; *Sundstrom v. County of Mendocino*, 202 Cal. App. 3d 296, 307.

In this case, there is no justifiable reason for delaying the study or not initiating the study at an earlier date. In September of 2001, in response to the Original EIS/EIR, the Inglewood Unified School District analyzed an abundance of studies and academic research regarding the relationship between aircraft noise and children’s learning, ‘learned helplessness’ and high blood pressure. LAWA does not present a satisfactory reason for its failure to conduct or initiate its proposed study at that time, nearly two years prior to release of the Supplement, or any time since then. Thus, the SEIS/EIR fails in its obligation to conduct the study at the earliest feasible stage in the process.

Also, as a result, the SEIS/EIR fails to meet the requirement of “completeness and a good faith effort at full disclosure.” (*Berkeley Keep Jets Over the Bay Committee v. Board of Port Commissioners* (2001) 91 Cal.App.4th 1344, 1355.)

iii. Failure to Conduct a Study Prior to Publishing the SEIR/EIR Is Against Public Policy.

The oversight in failing to conduct a noise study in and of itself may seem inconsequential, however, in face of overarching public policy considerations, it is significant. Public policy dictates that, “in the absence of overriding circumstances, the CEQA process demands that mitigation measures be timely set forth, that environmental information be complete and relevant, and that environmental decisions be made in an accountable arena.” (*Gentry v. City of Murrieta* (1995) 36 Cal.App.4th 1359, 1393-1394.) Otherwise, the process diminishes the influence of decisionmaking in CEQA by not allowing the public to review the environmental impacts and provide comments to the lead agency. “Public and agency review” has been called the “strongest assurance of the adequacy of the EIR. [Citations]” (*Sundstrom v.*

County of Mendocino (1988) 202 Cal. App. 3d 296, 308.) Absent this public review, LAWA is not accountable to mitigation measures for a significant impact caused by aircraft noise on children's learning.

Moreover, CEQA's very purpose "is to inform the public and its responsible officials of the environmental consequences of their decisions before they are made. Thus, the EIR 'protects not only the environment but also informed self-government.' [Citations.]" (*Berkeley Keep Jets Over the Bay Committee v. Board of Port Commissioners* (2001) 91 Cal.App.4th 1344, 1354.) The lack of early disclosure and public review completely disregards and undermines the CEQA process.

iv. The Proposed Noise Study Must Meet Stringent Scientific Standards to be Valid.

LAWA proposes to commission a study to determine a dose-response relationship between aircraft noise exposure and learning deficits in children. (SEIS/EIR, *Land Use*, Section 4.2, p. 4-210.) This is a worthy scientific endeavor that will entail a large, complex, and lengthy process that will cost an enormous sum of money. The proposed study will require considerable expertise, experience, and knowledge in formulating, conducting, analyzing and interpreting complex data. As currently described in the SEIS/EIR, it is impossible to evaluate the potential merits of the proposed study because major elements of the most basic scientific information are not presented about the study.

No scientific research proposal can be evaluated for its potential merit without a careful, even handed and critical review of the existing literature bearing on the topic. The current document provides an incomplete, outdated, and highly biased overview of the literature. It relies too heavily on one summary review (FICON). Furthermore no conceptual arguments are developed linking the literature overview with the proposed study. In scientific research, investigators must build a conceptual and methodological rationale for any proposed study. The current document does not do this.

The SEIS/EIR needs to include a statistical power analysis to estimate the number of participants to be included in the proposed study. Standard scientific review criteria for empirical research proposals call for statistical estimates of effect sizes from existing literature and their incorporation into research proposals. This power analysis would need to address the overall sample size for establishing a dose response function between noise and each learning outcome of interest. Furthermore, critical subsample power estimates would need to be incorporated such as ESL and non-ESL children, children suffering permanent and temporary hearing loss (a very common occurrence among elementary school children because of ear infections) and grade levels given likely age differences in susceptibility to adverse noise impacts on reading acquisition as well as speech perception. For example, according to ANSI:

"Limitations in vocabulary and in the ability to 'fill in the blanks' when partial communication occurs in difficult listening situations have been shown to reduce intelligibility for children with limited English Proficiency, again despite normal intelligibility in quiet environments. These children may require 2 to 5 dB more

favorable signal-to-noise ratios in difficult listening situations to achieve the same level of intelligibility as children with normal English proficiency. (Citations omitted.) (ANSI, "Acoustical Performance Criteria, Design Requirements, and Guidelines for Schools.")

In addition, ANSI estimates that hearing impairments caused by ear infections are,

"estimated incidence as high as 25% to 30% among kindergarten and first grade children. . . . Signal to noise ratio improvements of 3 dB to 5 dB together with increases in absolute speech sound levels of 10 dB to 30 dB are necessary for children with these impairments to achieve the same level of speech intelligibility in classrooms with high background noise." (ANSI, "Acoustical Performance Criteria, Design Requirements, and Guidelines for Schools.")

The research design of the proposed study would also need to address in detail how duration of exposure (e.g., months in residence) and home noise exposure would be incorporated into a study of schools varying in aircraft noise exposure.

Given a thorough statistical power analysis is needed to ensure that the appropriate number of participants are included overall and in critical subgroups in order to provide the necessary sensitivity to detect potential adverse effects, a thorough sampling plan also needs to be developed. The following issues must be addressed in the SEIS/EIR with respect to the proposed study: How and where will participants be sampled and what special sampling techniques will be used to ensure adequate representation of critical subgroups (e.g., ESL)? Will children with temporary or permanent hearing loss be included in the study and how will these classifications be determined? Will data be collected in one or multiple school districts and if the latter, how will differences in reading curricula be handled? Will data be collected only once, yielding a cross-sectional study or will a panel design be developed to monitor children's learning trajectories over time? If the latter research design is incorporated, at what ages would children be monitored and how often would data be collected? If a longitudinal design is incorporated, how will attrition be dealt with both in the research design and in data analysis?

No information is provided in the SEIS/EIR about the manner in which the proposed study would be conducted and what measures of learning would be incorporated. Is the primary focus on chronic or acute noise? This has dramatic implications for interpretation of the data and bears significantly on procedural conduct of the study itself. For example, reliance on archival records of standardized tests confounds chronic and acute noise exposure since the tests are taken during airport operational periods.

Outcome measures (e.g., reading acquisition, speech perception) need to be described, including at a minimum their basic psychometric properties (e.g., reliability, validity) and their appropriateness for use in a culturally diverse, multi-language sample.

How exactly will noise exposure be estimated and what metrics will be used? The SEIS/EIR glosses over critical distinctions in noise metrics such as L_{MAX} , L_{LEQ} , CNEL, and time above peaks. The authors of the proposed study need to say what metric(s) they would use and provide a rationale, discussing in depth the strengths and weaknesses of each alternative. How will reverberation time be monitored and incorporated into data analyses and interpretation. In interior settings, reverberation time influences speech intelligibility. The very difficult issue of exposure estimation also requires discussion. Where and when will noise exposure be measured? Children learn in the classroom, on the playground, and at home. A narrow focus on school noise level changes ignores the potential influence of changes in home noise levels caused by expanded airport operation.

There is no data analytic plan included in the study proposal detailing precisely how the results would be analyzed. Such a plan at a minimum would describe what statistical techniques would be used and how controls for factors with known covariation with noise and learning would be dealt with in the analyses. For example, how will the proposed study statistically or methodologically handle the co-mingling of income, ethnicity, noise exposure, and learning?

It is basic scientific practice to address the kinds of issues briefly summarized above in research proposals to obtain funding to conduct research. Scientific review panels for the National Science Foundation or the National Institutes of Health routinely consider and evaluate the scientific merits of proposals using such criteria. This is widely understood and supported by scientists. Major foundations that support scientific research subscribe to similar scientific review criteria as well. Written proposals that address the types of issues and questions raised above are typical, routine practice engaged in by scientists *prior to conducting research*.

Because the SEIS/EIR ties the proposed study to some critical policy decisions, it is critical to provide some additional material to the document under review. In particular, regulatory bodies and the public need to know more about how the results would be used to determine mitigation measures. For example, what indices of deficit would be considered significant and trigger mitigation? If reading acquisition is delayed on average by six months and for even longer for ESL children, would LAWA consider this sufficient to incorporate mitigation? What percentage of loss in speech perception is considered sufficient to warrant mitigation? Parallel questions need to be discussed for all health and welfare outcomes judged pertinent to the study design.

There is precedent in California and federal environmental regulatory procedures to incorporate a margin of safety in standards to protect vulnerable subgroups of the population. For example air pollution standards both in California and at the federal-level mandate protection for asthmatic children. (See Cal/EPA, *Staff Report: Public Hearing to Consider Amendments to the Ambient Air Quality Standards for Particulate Matter and Sulfates*. Air Resources Board and Office of Environmental Health Hazard Assessment, May 2002, <http://www.arb.ca.gov/research/aaqs/std-rs/pm-final/pm-final.htm>; see also, USEPA, *Review of the National Ambient Air Quality Standards for Particulate Matter: Policy Assessment of Scientific and Technical Information*. Office of Air Quality Planning and Standards, June 2001, <http://www.epa.gov/ttn/oarpg/t1/reports/pmstdrft.pdf>.) How will determinations be made of which groups of children are vulnerable and in need of additional protection from elevated noise

levels at school and in their homes? What margin of safety will be incorporated to protect these vulnerable subgroups, once determined?

Decisions about criteria for mitigation and protection of vulnerable subgroups in the population are both scientific and political. Since one of the major reasons for the proposed study in the SEIS/EIR is to determine mitigation procedures, government bodies with regulatory responsibility, as well as the public, must have the opportunity for discussion and review of the criteria that will be used to determine such critical policy decisions. The present document is silent on these issues therefore precluding regulatory and public scrutiny as mandated in CEQA and NEPA.

PART FOUR

THE EMISSIONS, MODELING, MITIGATION MEASURES AND HEALTH IMPACT ANALYSIS OF THE SEIS/EIR IS INADEQUATE

CEQA requires the EIS/EIR to "identify and focus on" significant environmental effects of proposed projects. (14 *California Code of Regulations* § 15126.2.) "Direct and indirect significant effects of the project on the environment shall be clearly identified and described, giving due consideration to both the short-term and long-term effects." (*Id.*) The EIS/EIR also must describe "feasible measures which could minimize significant adverse impacts." (14 *California Code of Regulations* § 15126.4.) The EIS/EIR fails to adequately do so.

1. The Emissions Estimations in the SEIS/EIR Violate CEQA.

The emissions estimates in the SEIS/EIR for jet aircraft and storage and handling of fuels may be underestimated. Correction of this underestimation will result in increased pollutant concentrations that may result in exceedances of the National Ambient Air Quality Standards (NAAQS) and California Ambient Air Quality Standards (CAAQS) as well as increases in off-site cancer risks and noncancer hazard indices for off-site populations.

a. Jet Aircraft Emission Estimates May Be Underestimated As the Methodology Used to Estimate Particulate Emissions from Jet Aircraft Is Unclear and May Be Flawed.

To estimate particulate matter less than 10 microns (PM₁₀) emission rates from aircraft for the EIS/EIR, Los Angeles World Airports (LAWA) used information from three sources: 1) fourth edition of AP-42; 2) Whitefield and Hagen Study; and 3) the 1994 California FIP Docket (Original EIS/EIR, Technical Report 4, Attachment H). The emission rate data from these studies are combined; the combined data are plotted for each of the four aircraft operating modes. Based on these plots, a relationship between fuel usage and PM₁₀ emission rate is interpolated.

A review of the data shows the first and second studies to be in approximate agreement; the FIP Docket provides an alternate data set. As there is approximately an order of magnitude

more FIP Docket data, the data from this study dominate the results. If the FIP Docket data were removed from the combined data set, it is clear that the relationship between fuel usage and the PM₁₀ emission rates would change and the estimated total PM₁₀ emissions from aircraft would also change.

Based on the information presented in the EIS/EIR, it is unclear how the FIP Docket data are used in the PM₁₀ emission rate analysis. It appears that a relationship between PM₁₀ emissions and fuel usage is derived from a graphical representation of a relationship between particulate mass concentration and smoke number (i.e., from a plot of an equation relating PM concentration and smoke number).

There are two issues with this derivation. First, it is not clear how a relationship between fuel usage and PM₁₀ emissions is derived from a plot of particulate mass concentration versus smoke number. Second, because the particulate mass concentration versus smoke number data appear to be simply a plot of some unknown equation, the number of data points taken from this graph seems to be arbitrary. Since the number of points taken from this graph is approximately 10 times greater than the number of data points available from the other two studies, it appears that LAWA may have arbitrarily weighted the combined data set heavily towards the FIP Docket data and away from the AP-42 and Whitefield and Hagen data.

Aircraft emissions of PM₁₀ are potentially underestimated. An increase in PM₁₀ emissions will result in an increase in off-site concentrations of PM₁₀. As noted below, the potential noncancer health impacts associated with these PM₁₀ emissions have not been quantified in the EIS/EIR. Inclusion of additional PM₁₀ emissions may result in exceedance of the noncancer hazard index for off-site populations.

At a minimum, LAWA needs to clarify the approach used to develop the FIP Docket data; conduct a sensitivity analysis to determine the importance of the FIP Docket data to their results; and, if necessary, remove arbitrary weighing of FIP Docket data over other data sets, correct the PM₁₀ emission rates, and remodel off-site PM₁₀ concentrations.

b. Potentially significant evaporative emissions of toxic air contaminants resulting from the storage and handling of organic liquids may not have been quantified.

LAWA does not include volatile organic compound (VOC) emissions from organic liquid storage and transfer in their Industrial Source Complex Short Term 3 (ISCST3) modeling of toxic air pollutant emissions. They assume that: 1) storage emissions are almost exclusively from Jet A fuel; 2) emissions of Jet A vapor do not contain significant quantities of the toxic air pollutants modeled; and 3) limited future operations of gasoline fueling would include vapor recovery and therefore result in minimal emissions of air toxics.

There are three problems with this exclusion of VOC emissions. First, diesel fuel and gasoline are used at the airport. LAWA should provide data to show that storage and resulting emissions of these fuels are insignificant. Second, LAWA should provide justification for the assumption of no toxic air pollutants in Jet A vapor. Third, LAWA should provide some

screening calculations to validate their assumption that gasoline fueling would result in insignificant emissions of air toxics (especially benzene).

Toxic air emissions from storage and handling of organic liquids may have been underestimated. An increase in toxic air emissions will result in increases in off-site cancer risks and noncancer hazard indices for off-site populations.

At a minimum, LAWA needs to quantitatively demonstrate that emissions of toxics from storage and handling of diesel fuel and gasoline are insignificant; and provide a speciated chemical list for Jet A fuel.

2. The Modeling Approach of the EIS/EIR Violates CEQA.

The modeling approach presented in the EIS/EIR has several significant flaws that result in underestimation of both criteria and toxic pollutants impacts on nearby receptors. The analysis of the emission impacts is inadequate, the methodology used to estimate plume rise is flawed, the assumption of no downwash is not justified, the meteorological data used in the modeling is inadequate, the conversion of sulfur dioxide to sulfate is not addressed, and finally, secondary formation of toxic pollutants and deposition effects are ignored. These flaws result in an underestimate of ambient pollutant concentrations. Correcting these flaws will result in an increase in pollutant concentrations and may result in exceedances of the NAAQS and CAAQS as well as increases in off-site cancer risks and noncancer hazard indices for off-site populations.

a. The methodology used to estimate plume rise from jet aircraft is questionable and requires further justification.

LAWA determines the plume rise of hot exhaust gas from jet aircraft engines based on a heat balance to determine the heat flux and the equivalent exit velocity that would result (Original EIS/EIR, *Technical Report 4*, p. 19). To calculate this exit velocity, they make four critical assumptions. First, the jet engine exhaust gas temperature is fixed and unrelated to the heat flux. Second, as the exhaust gas from the jet engine begins to slow (in the horizontal plane) and begins to move vertically upward as a plume, the diameter of the plume (in the vertical plane) may be estimated by the wingspan of the jet.

Third, the temperature of the plume is equal to the jet engine exhaust gas temperature. As there are no ambient heat sources, this implies that the movement of the exhaust gas is adiabatic, isothermal, and there is no rapid expansion of exhaust gas. Finally, the temperature of ambient air is assumed to be 293 Kelvin (K). Calculated exit velocity, plume temperature, and plume diameter were then input into ISCST3 to determine plume rise.

There are three problems with this approach. First, the temperature of the plume is assumed equal to the temperature of the exhaust gas. Given isothermal movement, this is only true if the total mass per second of air leaving the jet engines equals the mass per second of air moving up in the plume. LAWA should check their calculations to be sure that this is true, otherwise the plume rise calculations may be in error.

Second, the implied assumptions of isothermal movement and slow expansion of exhaust gas are physically unrealistic. It is likely that exhaust gas will expand rapidly when exiting the jet engine and cooler, ambient air will be entrained into exhaust gas as it moves away from the jet engine. Both of these effects will tend to lower the temperature in the plume. LAWA should perform a sensitivity analysis to determine the quantitative influence of these phenomena on the resulting plume rise.

Finally, the temperature of the ambient air should be consistent with the average temperature data used in the ISCST3 model runs. LAWA should average the temperatures in the meteorological data set used in the model runs to determine the correct average ambient temperature.

Plume rise may be overestimated. If so, concentrations of NO₂, PM₁₀, and air toxics resulting from aircraft emissions may be underestimated. Increases in concentrations of these pollutants may result in exceedances of the NAAQS and CAAQS as well as increases in off-site cancer risks and noncancer hazard indices for receptor populations.

At a minimum LAWA needs to check their calculations to ensure conservation of mass; conduct a sensitivity study to determine the quantitative influence of rapid expansion of exhaust gas and entrainment of ambient air on plume temperature; and calculate the plume rise with the correct average ambient temperature.

b. The assumption that building downwash is negligible requires further justification.

LAWA believes that building downwash will not be significant based on their assumption that the nearest receptor is too far off-site (Original EIS/EIR, *Technical Report 4*, p 24). LAWA should validate this assumption by modeling the most conservative source-receptor geometry, with building downwash included, to ensure this statement is correct. These results should be presented in *Technical Report 4*.

Off-site impact from airport emissions may be underestimated. If so, concentrations of criteria pollutants and air toxics resulting from airport emissions may be underestimated. Increases in concentrations of these pollutants may result in exceedances of the NAAQS and CAAQS as well as increases in off-site cancer risks and noncancer hazard indices for receptor populations.

LAWA needs to conduct a sensitivity study to show that building downwash effects are negligible.

c. The meteorological data set used may be inadequate relative to EPA and SCAQMD recommendations.

LAWA used the most recent meteorological data collected at LAX. These data consist of hourly surface and upper air data from the LAX meteorological observation station operated by the SCAQMD for the 12-month period beginning March 1, 1996 and ending February 28, 1997.

As recommended by EPA, "five years of representative meteorological data should be used when estimating concentrations with an air quality model. (USEPA, *Guideline on Air Quality Models (Revised)*. Office of Air Quality Planning and Standards, Research Triangle Park, NC 27711, EPA-450/2-78-027, 1986, August 1995 update.) Consecutive years from the most recent, readily available 5-year period are preferred." SCAQMD recommends the use of the 1981 dataset. Accordingly, LAWA should conduct their air modeling with either the most recent five years of data from the LAX station, selecting the most conservative year results as representative of maximum long-term pollutant concentrations resulting from emissions associated with LAX or use the 1981 dataset. Furthermore, this five-year data set or 1981 dataset should be used to estimate average temperature (plume rise), mixing heights (EDMS), and wind speed (volume source height) used in other calculations and analyses.

Pollutant ambient air concentrations may be underestimated. If so, concentrations of criteria pollutants and air toxics resulting from emissions associated with expansion of LAX may be underestimated. Furthermore, the location of the maximum off-site impacts may also change. Increases in concentrations of these pollutants may result in exceedances of the NAAQS and CAAQS as well as increases in off-site cancer risks and noncancer hazard indices for receptor populations.

At a minimum LAWA needs to (1) conduct a sensitivity study to determine which year of LAX meteorological data is the most conservative or use the SCAQMD designated 1981 year of data; (2) if different from the meteorological data used in their analysis, redo all air modeling with the correct meteorological data; and (3) use the most conservative meteorological data set to estimate meteorological data used in other calculations and analyses.

d. Atmospheric conversion of sulfur dioxide to sulfate may be significant and is not addressed.

LAWA has ignored production of sulfate from sulfur dioxide (SO₂) due to the complexity of sulfate-formation mechanisms. LAWA assumes that all sulfur emitted by sources remains in the atmosphere as SO₂. This assumption is not conservative; the California Ambient Air Quality Standard (CAAQS) for sulfate is more than six times lower than the CAAQS for SO₂ (6.2 parts per billion by volume (ppbv) compared to 40 ppbv).

Formation chemistry for conversion of nitrogen oxides (NO_x) to nitrogen dioxide (NO₂) is equally complex, if not more so. The Tier 2 Ambient Ratio Method (ARM) recommended by USEPA in the *Guideline on Air Quality Models* for converting total NO_x to NO₂ values may be modified to estimate formation of sulfate from SO₂. (USEPA, *Guideline on Air Quality Models*,

supra.) LAWA could gather the most recent years of data on the annual average SO₂-to-sulfate ratio near LAX and use this data to estimate the formation of sulfate.

The concentration of sulfate in ambient air is underestimated. Increases in concentrations of sulfate may result in an exceedance of the CAAQS for sulfate. As exposure to sulfate causes respiratory irritation, underestimating the ambient sulfate concentration may significantly underestimate the numbers and types of respiratory illnesses that may be observed in nearby populations, particularly young children who may be especially sensitive to respiratory irritants.

At a minimum LAWA needs to develop an approach to model sulfate chemistry and estimate sulfate concentrations.

e. Secondary formation of toxic air pollutants may be significant and is not addressed.

LAWA has ignored the production of several toxic air pollutants formed in the atmosphere due to reactions among other pollutants (i.e., formed by secondary reactions). As outlined in the EPA's guidance on Air Dispersion Modeling of Toxic Pollutants in Urban Areas, these pollutants should be included in any air toxic analysis. (United States Environmental Protection Agency (USEPA), Draft Air Dispersion Modeling of Toxic Pollutants in Urban Areas - Guidance, Methodology and Example Applications. Emissions, Monitoring and Analysis Division (MD-14), Office of Air Quality Planning and Standards, Research Triangle Park, NC 27711, EPA-454/R-99-021, July 1999, Original EIS/EIR Response Exhibit 12.) The pollutants formed by secondary reactions include formaldehyde, acetaldehyde and acrolein.

For example, formaldehyde may be formed in the atmosphere through photolysis or oxidation of other, directly-emitted hydrocarbon species:

An estimate of concentrations based on secondary reactions is needed and should be added to the ISCST3 output. LAWA should use EPA's OZIPR screening model to estimate the secondary formation of these pollutants. (USEPA, *Draft Air Dispersion Modeling, supra.*) Case studies provided in EPA's guidance document show secondary formaldehyde as the major component of total atmospheric formaldehyde (a ratio of 4 to 1 over primary formaldehyde).

If the total ambient formaldehyde concentration attributable to the project were increased by a factor of 5 to account for secondary formation, the contribution from formaldehyde to total absolute cancer and noncancer risks would increase by the roughly the same factor for all

years/alternatives. The absolute contributions of formaldehyde to total cancer and noncancer risks in different years/alternatives are not presented in the SEIS/EIR (see comment 4[f]).

The concentrations of formaldehyde, acetaldehyde and acrolein in ambient air are underestimated. Increases in concentrations of these pollutants may result in increases in off-site cancer risks and noncancer hazard indices for receptor populations. At a minimum LAWA needs to model formaldehyde, acetaldehyde and acrolein chemistry.

f. The exclusion of deposition effects from the multipath risk analysis is not justified.

LAWA has neglected to include deposition effects and associated multipathway risk analysis based on conclusions presented in the deposition report, included as Attachment Y to Original EIS/EIR *Technical Report 4*. In this report, LAWA claims that a direct correlation between airport operations and deposition could not be determined.

Nonetheless, LAWA goes on to state, "The limited monitoring duration [less than two weeks] and time of year, while required to meet project schedule requirements, were not optimal for dry deposition monitoring. The *limited nature* [italics added] of this study did not allow for the determination of summertime maximum deposition rates or provide data necessary to perform a mass balance analysis" (Original EIS/EIR, *Technical Report 4*, Attachment Y). LAWA is stating that the study was too short to make *any definitive conclusions* and further deposition sampling will be required before the deposition impact of airport emissions on off-site soils can be quantified. In other words, the study is incomplete.

If the study is limited and incomplete, there is no rational reason why LAWA should exclude deposition effects and the associated multipathway risk analysis. Furthermore, the deposition sampling locations selected for this study appear to be outside of the maximum particulate matter plume predicted by LAWA's ISCST3 modeling, further undercutting the already limited nature of this deposition study. Therefore, pending a more complete deposition study, LAWA should include deposition effects and a multipathway risk analysis in the EIS/EIR.

Deposition effects have been improperly excluded from consideration. Soil concentrations of pollutants sorbed to particulate matter have been underestimated. Increases in soil concentrations of these pollutants may result in increases in off-site cancer risks and noncancer hazard indices for receptor populations.

At a minimum LAWA needs to estimate concentrations of pollutants sorbed to particulate matter in soil based on emissions occurring over the duration of the project; and based on these soil concentrations, run a multipathway risk analysis to determine the health impacts of these soil concentrations.

3. The Mitigation Measures Proposed By The SEIS/EIR Violate CEQA.

- a. The mitigation measures proposed in the SEIS/EIR have not met all requirements outlined in the SCAQMD CEQA Handbook.**

The mitigation measures proposed in the SEIS/EIR have not met all requirements outlined in the SCAQMD CEQA Handbook. Before mitigation measures may be applied to total project emissions they must meet several criteria. The mitigation measures proposed in the SEIS/EIR have not demonstrated compliance with three of these criteria.

Several proposed mitigation measures do not meet the required criteria. Therefore, mitigated emission estimates may be too low. Increases in emissions of mitigated pollutants may result in exceedances of the NAAQS and CAAQS as well as increases in off-site cancer risks and noncancer hazard indices for receptor populations. Furthermore, without mitigation measures, the proposed project under Alternatives A, B, and C will result in exceedances of regulatory thresholds for criteria and/or toxic pollutants (SEIS/EIR Table 4.24.1-3).

At a minimum LAWA needs to (1) develop a matrix showing each mitigation measure and how it meets each of the three missing criteria identified above; and (2) improve documentation of the effectiveness of the selected mitigation measures used to reduce pollutant emissions.

- b. Mitigation measures, except those specific to construction activities, should be applied towards the No Action/No Project alternative in addition to Alternatives A, B, C, and D.**

Mitigation measures are defined in SEIS/EIR Section 4.6.8, including Table S.4.6-18. With the exception of those measures specific to construction activities, the identified measures may be implemented under the No Action/No Project alternative as well as Alternatives A, B, C, and D. For example, the following mitigation measures identified in Table S.4.6-18 are generally applicable to all alternatives including No Action/No Project:

Airside

Convert GSE to electric power

Clean Vehicle Fleets

Promote commercial vehicles/trucks/vans using terminal areas to install SULEV/ZEV engines

Promote "best-engine" technology for rental cars using on-airport RAC facilities.
Consolidate nonrental car shuttles using SULEV/ZEV technology

Energy Conservation

Cover any parking structures that receive direct sunlight to reduce volatile emissions from vehicle gasoline tanks and install solar panels on these roofs where feasible to supply electricity or hot water

Highways and Roadways

Link ITS with off-airport parking facilities, with ability to direct/divert trips to these facilities

Expand ITS/ATCS, concentrating on I- and I- corridors, extending into South Bay and Westside surface street corridors

Link LAX traffic management system with airport cargo facilities, with ability to reroute cargo trips to/from these facilities

Develop a program to minimize the use of conventional-fueled fleet vehicles during smog alerts

Landside

Contract with commercial landscapers who operate lowest emitting equipment

Parking

Provide free parking with preferential parking locations for ULEV/SULEV/ZEV in all (including employee) LAX lots; provide free charging stations for ZEV; include public outreach

Pay-on-foot (before getting into car) to minimize idle time at parking check out; include public outreach

Implement on-site circulation plan in parking lots

Promote employee rideshare opportunities

Encourage employee telecommuting

Provide video-conference facilities

Transit and Intermodal

Establish network of strategically placed, off-airport intermodal check-in terminals serviced by LAX-dedicated clean-fuel buses; provide low-priced parking to LAX users of off-airport intermodal terminal facilities; include public outreach

As noted in Part Four, Section (g), *infra*, the logical basis for evaluation of project significance under Alternatives A, B, C, or D in a future year (e.g., 2015) is the No Action/No Project alternative in the same future year. For such a comparison, it is appropriate that non-construction mitigation measures be applied towards both the build and no-build alternatives, as it is possible if not likely that these measures will be implemented regardless of which alternative is pursued. Application of non-construction mitigation measures to only the build alternatives, as is currently done, would incorrectly favor the build alternatives over the no-build alternative.

4. The Health Risk Analysis of the EIS/EIR Violate CEQA.

The flaws in the health risk analysis conducted for the EIS/EIR result in underestimated acute, cancer, and noncancer health impacts. Estimated cumulative cancer risks to school children are underestimated, cumulative cancer risks and noncancer hazards are incorrectly calculated, the significance threshold for noncancer health effects is too high, potential health impacts associated with exposure to lead are improperly calculated, potential health impact from jet engine particulate emissions are ignored, noncancer health risks to school children are underestimated, and acute health impact are not evaluated. These flaws result in an underestimation of the health impacts to receptors of concern.

- a. **Estimated cumulative cancer risks to school children have been underestimated due to underestimates in the total number of years children spend in school.**

The *Human Health Risk Assessment* (HHRA) estimated the potential incremental cancer risks for children attending schools by identifying the school with the highest projected concentrations of toxic air pollutants, and determining the total length of time that children would likely be at school. Approximately 20 schools were identified as being within one mile of LAX; Oak Street Elementary School was identified as one of the schools where the highest concentrations of Toxic Air Pollutants (TAPs) released from LAX were predicted.

Children ages 6 to 12 years old were evaluated in the HHRA, since "this age range includes the youngest school ages and it is sufficiently long for analysis of chronic exposures and risks" (Original EIS/EIR, *Technical Report* 14a, Attachment B, p. 42). Accordingly, children in school were assumed to be exposed to emissions from LAX for six years.

However, given that children will, in fact, be in school from ages 5 to 18 years (kindergarten through 12th grade), and that the future development of schools within the impacted area is unknown, it is very likely that children could be exposed to emissions from LAX for a 13-year period (corresponding to kindergarten through 12th grade). As estimates of cancer risk are directly proportional to the total time that an individual is exposed over the course of the lifetime, the assumption that school children are only exposed for six years is misleading, and results in an underestimate of the potential incremental cancer risks posed by children attending school.

Cancer risks for school children are underestimated in the EIS/EIR. Cancer risks should be recalculated for the school children to account for the potential that children could be exposed to emissions from LAX during their entire pre-school through high school years.

b. Significant flaws in the methods used to calculate cumulative cancer risks and noncancer hazards undermine the conclusions of the EIS/EIR and obscure actual health risks posed by the various alternatives.

The HHRA repeatedly touts the benefits of all build alternatives, stating that with mitigation, "all of the build alternatives would have lower (more favorable) human health impacts than those associated with the No Action/No Project Alternative" (Original EIS/EIR, p. 4-999). Many of the tables and text describing the incremental cancer risks and noncancer hazards actually present negative risks, indicating not only a reduction in risks below those associated with baseline conditions, but a "beneficial impact on LAX-associated cancer risks" (or noncancer hazards) (Original EIS/EIR, *Technical Report 14a*, p. 51). Such statements are not only misleading, they are technically inaccurate.

For example, some of the projected increase in cancer risk for some chemicals for Alternative D 2015 pre-mitigation conditions (SEIS/EIR, *Technical Report 9a*, Table S8) (e.g., diesel particulates, formaldehyde, benzene) is claimed to be offset by a projected decrease in cancer risk for other chemicals (arsenic, beryllium, and chromium).

The fundamental flaw in this logic is the assumption that a decrease in the concentration of one carcinogenic compound can offset the increase the concentration of another carcinogen. If the implementation of a given alternative results in lower concentrations of diesel exhaust than would occur under the baseline conditions, then the incremental contribution of diesel to the total cancer risk drops to zero. However, a net reduction in diesel is not "credited" against the likelihood that increases in other chemicals may cause cancer in exposed individuals.

To illustrate this point, assume two chemicals exist, say 1,3-butadiene and benzene, and the baseline cancer risks are 10×10^{-6} for each chemical. If the projected cancer risk under Alternative A is 13×10^{-6} for 1,3-butadiene and zero for benzene, the projected incremental cancer risk is $+3 \times 10^{-6}$ for 1,3-butadiene and the projected incremental cancer risk from benzene would be presented as -10×10^{-6} (indicating that the concentrations of benzene under Alternative A drop below the baseline concentrations), the cumulative risk from both compounds is NOT -7×10^{-6} , as would be presented in this HHRA, it is 13×10^{-6} . Independent of any projected improvement in diesel risks, 1,3-butadiene is still projected to cause an increase in cancer risk of $+3 \times 10^{-6}$.

In other words, if the projected incremental cancer risk posed by 1,3-butadiene is $+3 \times 10^{-6}$ and the projected incremental cancer risk from diesel is presented as -14×10^{-6} (indicating that the concentrations of diesel under the alternative drop below the baseline concentrations), the cumulative risk from both compounds is NOT -11×10^{-6} , as presented in this HHRA, it is $+3 \times 10^{-6}$. Independent of any projected improvement in diesel concentrations, 1,3-butadiene is still projected to cause an increase in cancer risk of 3×10^{-6} . (Data values taken from Original EIS/EIR, *Technical Report 14a*, Table 13, Alternative A, Adult Resident.)

Potential health impacts have been improperly summed. This fundamental flaw permeates the HHRA, and results in underestimates of the potential health impacts of all alternatives. As currently presented, it is impossible to evaluate each of the alternatives to

determine which alternatives may pose a significant health threat, or to ascertain whether the proposed mitigation measures will be sufficient to reduce the health risks to insignificant levels.

The Inglewood Unified School District recommends that LAWA correct these errors and recalculate the risks for all alternatives.

c. The basis for significance threshold for noncancer health effects is unclear and five times greater than the threshold typically used by regulatory agencies.

A significant impact relative to human health is defined in the Original EIS/EIR as a build alternative that would result in a total incremental chronic hazard index (HI) greater than 5 for any target organ system at any receptor location (Original EIS/EIR, p 4-1009). The basis for this significance threshold is unclear, is inconsistent with statements made in the *Human Health Risk Assessment Technical Report*, and is considerably less protective than acceptable thresholds established by regulatory agencies under various regulatory programs.

As described in the Original EIS/EIR, noncancer risk estimates are calculated by dividing the estimated exposure by the "reference dose," often referred to as the acceptable exposure level (Original EIS/EIR, *Technical Report 14a*, p 28). The ratio of the exposure to the reference dose is termed the hazard quotient (HQ). To assess the overall potential for noncarcinogenic effects posed by more than one chemical, the HQs for each chemical are summed, and the resulting value is referred to as the Hazard Index (HI).

As stated in the Original EIS/EIR, "a HQ greater than one indicates an exposure greater than that considered safe" (Original EIS/EIR, *Technical Report 14a*, p. 28). This conclusion is consistent with thresholds established by USEPA and Cal/EPA under the *Comprehensive Environmental Response, Compensation, and Liability Act* (CERCLA), and California's Toxic Hot Spots program (AB2588), respectively. Similarly, an overall HI of no greater than one is the threshold that is used by Cal/EPA in determining whether conditions at a site could potentially result in unacceptable adverse noncancer health effects. Sites for which the multichemical HI is greater than one typically trigger further investigation, and often remediation.

The significance threshold used in this EIS/EIR to evaluate the potential for adverse noncancer health effects is five times higher (i.e., five time less protective) than noncancer thresholds typically used by regulatory agencies under various state and federal regulatory programs. It is unclear how and why a different and less protective standard is being used to evaluate the potential health impacts associated with the various build alternatives. If the more standard noncancer HI threshold of one were used to evaluate the significance of the various alternatives, the conclusions of each of the build alternatives, and the corresponding need for mitigation, would be different than is currently presented.

For example, under Alternative B in 2015, "people living in an area immediately east of the north runways might be exposed to TAPs from LAX sufficiently to produce a hazard index above [5]. People living in a larger area extending east-northeast from the LAX theme building over 6 miles would be exposed to sufficient concentrations of TAPs to produce an incremental

hazard index between 1 and 5" (Original EIS/EIR, p. 4-1014). Thus, the number of people subjected to unhealthy levels of toxic chemicals may be greatly understated by the EIS/EIR.

The effect that establishing the threshold hazard index at 1 would have on the conclusions of the Alternative D analysis is unclear. The Inglewood Unified School District has commented elsewhere that the manner in which incremental risks under the project build alternatives are calculated and expressed in the EIS/EIR is inappropriate (i.e., use of negative risks, selection of 1996 as baseline, methodology for calculating baseline risks). If Alternative D risks were redefined and recalculated as suggested, and if the threshold index were established at 1 per standard practice, then estimated noncancer risks may exceed the significance threshold.

LAWA should rewrite the discussion of noncancer risks, and clearly identify those alternatives that would be considered significant based on the more appropriate noncancer significance threshold of one.

d. The EIS/EIR fails to consider and evaluate the potential health impacts associated with exposure to lead.

As described in the EIS/EIR, lead "may be released in significant quantities from LAX" (Original EIS/EIR, *Technical Report 14a*, Attachment B, p. 19). The potential impacts associated with exposure to lead are typically evaluated by using models developed by both USEPA and Cal/EPA to predict the blood-lead level that would result from a given exposure.

Because children are especially sensitive to the neurological effects of low levels of lead exposure, these models are used to estimate the blood-lead levels in children. The results from the model are then compared to the low blood-lead levels that have been demonstrated to result in subtle neurological damage in children, as established by the Center for Disease Control (CDC). The models are easy to use, have been used for more than eight years, and are considered the industry standard for evaluating lead exposures and determining whether such exposures could result in unacceptable health impacts.

Although the EIS/EIR notes that LAX may release significant quantities of lead, the EIS/EIR does not evaluate the impacts of such releases in accordance with the standard industry practice. Instead, the EIS/EIR compares the predicted concentrations of lead to the Ambient Air Quality Standard, and concludes that, because the concentrations are below the Ambient Air Quality Standard, lead is not a toxic air pollutant (TAP) of concern for the LAX Master Plan (Original EIS/EIR, *Technical Report 14a*, Attachment B, p. 12).

Such treatment of lead significantly diminishes the public health significance of this TAP, and does not allow for a fair determination as to the public health impacts that may result from the various build alternatives. Any risk assessment submitted to either Cal/EPA or the USEPA would be instantly rejected if conclusions about the public health significance of lead were based solely on a comparison to the Ambient Air Quality Standard.

Further, the EIS/EIR states that a cancer slope factor is not available for lead (Original EIS/EIR, *Technical Report 14a*, Attachment B, pp. 18-19). The Inglewood Unified School

District notes that the Cal/EPA Office of Environmental Health Hazard Assessment (OEHHA) has released a cancer slope factor for lead. The cancer slope factor, although not yet a promulgated standard, is available, and is being used by OEHHA to establish the No Significant Risk Level (NSRL) for lead under California's Proposition 65.

Health impacts resulting from lead in all years/scenarios, including Alternative D, may be underestimated. Because of the heightened public awareness to the risks associated with lead exposure and the plethora of information that exists describing the adverse health effects that can result from lead exposure, lead should be evaluated in this EIS/EIR in the most comprehensive manner that is reasonably practicable. Failure to do so is scientifically unjustifiable and is inconsistent with the more rigorous evaluations conducted for other chemicals included in the HHRA.

LAWA should rerun all health risk calculations to determine the human health implications of the increases in lead emissions that will result from all build alternatives.

- e. **Excluding particulate emissions from jet aircraft from the quantitative risk evaluation could significantly underestimate the potential for noncancer health impacts.**

Particulate emissions from aircraft were not quantified in the HHRA because "there is insufficient information regarding the nature and toxicity of total petroleum hydrocarbon (TPH) emissions associated with aircraft and toxicity criteria for these emissions are not available" (Original EIS/EIR, *Technical Report 14a*, p. 81). Particulate matter, in the form of diesel exhaust, is emitted from several ground sources (predominantly trucks and buses). Emissions of diesel exhaust from these ground sources have been included in the HHRA. However, the EIR states that because aircraft use a different fuel and a substantially different combustion process than diesel engines, the particulate emissions in jet exhaust are "not considered chemically, physically, or toxicologically similar to diesel exhaust" (Original EIS/EIR, *Technical Report 14a*, p. 12). Accordingly, the impact of such emissions have not been quantified in the HHRA.

This is the logic set forth in the EIS/EIR for excluding jet particulate emissions from the HHRA. The argument, however, for not being able to evaluate the toxicological effects of particulate exhaust from jets is flawed. Functionally, the methods used to evaluate the noncarcinogenic toxicity of "diesel" are based entirely on the particulate matter present in diesel exhaust.

According to USEPA, the systemic (non-cancer) toxicity of diesel emissions is due to the insoluble carbon core of diesel particles; when the exhaust is filtered to remove the particulate matter, the remaining exhaust mixture does not produce long-term toxicological effects in laboratory animals. The mechanism of toxicity of the carbon core relates to the deposition of the particles deep in the lung, and the accumulation and aggregation of these particles that result from the inability of the lung's normal clearance mechanisms to effectively remove the particles from the deep regions of the lung. The accumulation of particles sets off a pathogenic sequence that may result in the presence of pulmonary inflammatory, fibrotic, or emphysematous lesions.

(United States Environmental Protection Agency (USEPA), *Integrated Risk Information System*, On-line database maintained by USEPA, 2001.)

Because the noncancer toxicity associated with diesel exhaust is believed to be attributable entirely to the insoluble carbon core of the particulate matter, the noncancer toxicity factor would be equally applicable to other sources of particulate matter, such as jet fuel exhaust. If one can estimate the quantity of particulate matter that could be released from the exhaust of a jet engine, then use of the noncarcinogenic toxicity criteria for diesel is a scientifically defensible and appropriate method for evaluating the public health significance of the particulate emissions. Given the significant increase in the air traffic at LAX, failure to quantify potential impact associated with particulate emissions from jet aircraft could represent a significant omission from the estimated noncancer impacts.

The fact that particulate emissions from aircraft engines may be different than those from diesel engines is not adequate justification for ignoring the cancer health risks of aircraft particulate emissions entirely. It is reasonable to assume, given the lack of information to the contrary, that aircraft particulate emissions *are* similar to diesel emissions with respect to cancer effects. If this assumption were false, and aircraft particulates were in fact less carcinogenic than diesel exhaust, then the result would represent a conservative upper bound of the cancer risk posed by aircraft particulate matter. The existing estimate of risk posed by aircraft particulates, i.e. zero, could be considered a lower bound.

Data presented in Attachment W to *Technical Report 4* of the Original EIS/EIR indicate that aircraft contribute approximately 45 percent of total LAX operational PM₁₀ emissions within the LAX local area. If one makes the assumption that the cancer and noncancer toxicity of aircraft PM₁₀ emissions are similar to that of diesel particulates, they would conclude that the cancer and noncancer risks posed by operational PM₁₀ emissions may be underestimated by roughly a factor of 2 in all years/alternatives. The relative contributions of particulate matter to total cancer and noncancer risks in different years/alternatives are not presented in the SEIS/EIR (see Part Four, Section 4g., *infra*).

Health impacts from particulate matter may be underestimated. The Inglewood Unified School District recommends that LAWA recalculate all estimates of noncancer risk, and include in the evaluation the potential adverse health effects that can result from exposure to particulate emissions from jet aircraft.

f. Absolute cancer and noncancer risks are not presented in the EIS/EIR.

Cancer and noncancer risks are quantified solely on an incremental basis relative to 1996 risks, which themselves are not presented. The impression received is that presentation of absolute risk numbers is being avoided, presumably because they are large and may cause alarm.

- g. The EIS/EIR does not consider child-specific noncancer toxicity criteria which have been proposed by the State of California and are intended for use in the risk assessment of California school sites. Noncancer health risks to schoolchildren may be underestimated accordingly.**

Cal/EPA has issued proposed child-specific chronic reference doses (chRfDs) for six chemicals of particular concern to the health of schoolchildren: cadmium, chlordane, heptachlor, heptachlor epoxide, methoxychlor, and nickel (Cal/EPA, *Development of Health Criteria for School Site Risk Assessment Pursuant to Health and Safety Code Section 901(g): Proposed Child-Specific Reference Doses (chRfDs) for School Site Risk Assessment - Cadmium, Chlordane, Heptachlor/Heptachlor Epoxide, and Nickel*. Draft Report. Integrated Risk Assessment Section, Office of Environmental Health Hazard Assessment, June 2003, Exhibit 28). The proposed child-specific RfDs are generally more conservative than the US EPA RfDs used in the EIS/EIR health risk assessment, as shown in the following table.

Chemical	Proposed chRfD (mg/kg-d)	USEPA RfD (mg/kg-d)	Ratio
Cadmium	1 x 10 ⁻⁵	5 x 10 ⁻⁴	50
Chlordane	3.3 x 10 ⁻⁵	5 x 10 ⁻⁴	15
Heptachlor	3 x 10 ⁻⁵	5 x 10 ⁻⁴	17
Heptachlor epoxide	1.3 x 10 ⁻⁵	1.3 x 10 ⁻⁵	1
Methoxychlor	2 x 10 ⁻⁵	5 x 10 ⁻³	250
Nickel	3.7 x 10 ⁻³	2 x 10 ⁻²	5

The proposed chRfDs were developed by Cal/EPA specifically for the protection of schoolchildren and are intended for use in the risk assessment of California school sites. Thus, these toxicity criteria are appropriate for use in the EIS/EIR health risk analysis of noncancer impacts to offsite school children.

As the relationship between reference dose and noncancer health risk (hazard quotient) is linear, use of these chRfD values would result in an increase in the estimated noncancer health risk to school children from each of the listed chemicals, by the amount (ratio) given in the table. For example, the estimated noncancer health risk to school children posed by cadmium would be 50 times greater if the chRfD value were used.

Only one of the six listed chemicals is identified as a chemical of potential concern (COPC) in the EIS/EIR health risk assessment: cadmium. However, use of these RfD values may cause additional chemicals to be added to the group of COPCs. For example, an increase in the estimated health risk from methoxychlor by a factor of 250 may elevate this chemical to the status of potential concern.

At a minimum, the EIS/EIR health risk analysis should consider these toxicity criteria in an uncertainties section, and assess to what extent adoption of these criteria would affect the conclusions of the health risk assessment.

- h. Use of 1996 as basis for determining project significance is not explained and seems illogical.**

Significance of project impacts under build scenarios in future years is evaluated by comparison to 1996 "baseline" conditions and, in the SEIS/EIR, to 2000 conditions. The rationale for this is not clear. To evaluate project impacts for, e.g., Alternative D in 2015, it seems more logical to compare Alternative D 2015 conditions to No Action/No Project 2015 conditions. In this manner, the effects of the project may be directly quantified.

- i. Methodology for establishment of baseline (1996) impacts is poorly defined and highly suspect. All determinations of significance of Alternative D through comparison to 1996 baseline impacts are therefore questionable.**

According to the Original EIS/EIR, 1996/baseline impacts were not estimated directly but rather were derived by adjusting model predictions under the 2005 no-build alternative:

"Baseline conditions were not separately modeled. Instead, air quality for the baseline year (1996) was estimated from results of air dispersion modeling for the No Action/No Project Alternative for horizon year 2005...Thus, emissions estimates for 1996 were derived by subtracting out emissions associated with the No Action/No Project Alternative in 2005" (Original EIS/EIR, p. 4-1007).

The Inglewood Unified School District notes that the 1996 emissions inventory is the basis for all other inventories, including the 2005 No Action/No Project Alternative inventory, and therefore assumes that the final sentence in the above citation is a misstatement. It infers that 1996/baseline chemical concentrations were derived by scaling the chemical concentrations predicted by the air dispersion model for the 2005 No Action/No Project Alternative. The EIS/EIR does not document or support this scaling operation. The Inglewood Unified School District is unaware of any way in which a modeled concentration field may be scaled other than by uniform application of a constant factor (all values in a given chemical concentration field multiplied by the same factor). Therefore, it appears that any source-specific (i.e., spatial) differences between the 1996 and 2005 inventories were lost in the scaling process.

The EIS/EIR does not explain or support the rationale for not simply estimating baseline impacts directly, by using the 1996 inventory as input to the dispersion model. The indirect method apparently employed is inferior to direct modeling of 1996 impacts, because it results in a loss of spatial resolution of chemical emissions and resulting airborne concentrations. As the 1996/baseline impacts are the basis for determination of significance of the project, the process by which these baseline impacts were estimated should be thoroughly described. From the sparse and confusing discussion provided, it appears that the 1996 impacts were roughly fudged. Therefore, the Inglewood Unified School District holds significance determinations based on these 1996 impacts to be generally questionable.

- j. Alternative D post-mitigation incremental cancer risk to adult residents may be greater than 10 per million individuals.**

Table S4.24.1-5 of the SEIS/EIR indicates that the post-mitigation incremental cancer risk to adult residents is 2 per million individuals, below the significance threshold of 10 per million individuals. However, given that (see other comments) 1) cancer risk posed by secondary pollution is ignored, 2) cancer risk posed by aircraft particulate matter is ignored, 3) cancer risk posed by lead is ignored, and 4) the 1996 baseline cancer risk is highly suspect, the actual Alternative D post-mitigation incremental cancer risk may exceed the significance threshold of 10 per million individuals.

- k. Statement that acrolein noncancer risks are substantially overestimated in the EIS/EIR analysis is not supported by the arguments presented.**

"Emissions estimates for acrolein are based on available data that were generated from old aircraft engines not generally in use today and using military fuel that differs from fuel used at LAX" (SEIS/EIR, *Human Health Risk Assessment*, p. 4-615). This statement implies that newer aircraft using civilian fuel emit less acrolein than estimated. However, the implication is not supported by any other information.

"Acrolein is not generally recognized as a significant TAP in the South Coast Air Basin . . ." (p. 4-615). Prior recognition is not relevant or required. Further, this statement is contradicted by results of the USEPA study, which suggest that "hazard indices might fall in the range of 3 to 10 for chronic exposure to acrolein. . ." (SEIS/EIR, *Human Health Risk Assessment*, p. 4-619).

"A recent study near Chicago's O'Hare Airport failed to detect acrolein in essentially all samples taken in communities near the facility. . ." (SEIS/EIR, *Human Health Risk Assessment*, p. 4-615). Without discussion of sampling and analysis methods, especially of comparison of method detection limits to levels of concern, this statement is meaningless.

"The analysis presented for acrolein in the HHRA may substantially overestimate releases, and thus may overestimate possible chronic and acute impacts to human health. . ." (SEIS/EIR, *Human Health Risk Assessment*, p. 4-615). For the reasons noted above, the Inglewood Unified School District does not believe that sufficient evidence is presented in the EIS/EIR to justify this statement that acrolein impacts are overestimated in the HHRA.

- l. Use of different receptor/grid spacing when calculating pre- and post-mitigation impacts prevents assessment of mitigation effectiveness.**

"A greater number of endpoints were assessed for post-mitigation conditions than for pre-mitigation conditions to ensure that the highest post-mitigation impacts were identified. As such, post-mitigation risks and hazard estimates represent conservative estimates which are in some cases greater than pre-mitigation risks. . ." (SEIS/EIR, *Human Health Risk Assessment*, p. 4-617).

Increasing the receptor density does not *ensure* that the highest post-mitigation impacts are identified, it only increases the likelihood that they are identified. The additional data points likely include both lesser and greater values than would be predicted if only the smaller number of endpoints were considered. With both endpoint sets, it is possible, if not likely, that the greatest impacts (highest risk values) are not identified; however, this possibility is lower for the larger, post-mitigation endpoint set.

As noted, estimated post-mitigation risks in some cases are higher than pre-mitigation risks. This apparent increase in risk is likely an artifact caused by the larger number of endpoints used in the post-mitigation modeling. Comparison of pre- and post-mitigation impacts should be made with the same endpoint set (i.e., same group of receptors), to measure mitigation effectiveness.

PART FIVE

THE TRAFFIC IMPACT ANALYSIS IS INADEQUATE

To address traffic impacts of the LAX Master Plan on the Inglewood Unified School District, the SEIS/EIR should identify those locations where project traffic could cause significant impacts. In this regard it is typical for a traffic study to have clearly defined performance criteria with respect to how the study area is defined and the definition of "significant impact" within that study area. While the study area has been expanded since the Original EIS/EIR, it is not clear whether the expanded area of impact within Inglewood has been selected in this manner.

For example, it would seem that major roadway facilities such as Century Boulevard, Arbor Vitae Street and Manchester Boulevard would be affected in some manner by the Master Plan. All of these roadways, directly or indirectly, serve schools within the Inglewood Unified School District, and except for Prairie Avenue/Lennox Boulevard intersection no analysis was carried out east of La Brea Avenue. The traffic study is deficient in not addressing locations in this immediately adjacent area.

Even if the impacts are less than significant, there should have been some evaluation in the SEIS/EIR showing how the study area was selected and indicating findings of significance or no significance on roadways within the Inglewood Unified School District.

1. Lennox Interchange.

The addition of an interchange with I-405 at Lennox Boulevard is being proposed as a mitigation measure for Alternative D. The secondary impacts of this interchange on the Inglewood street system needs to be studied since the accompanying closure of Lennox Boulevard just east of the freeway will divert traffic to parallel streets such as Century Boulevard and Arbor Vitae Street.

2. Other Considerations.

There are numerous other issues related to the impact of Alternative D on the City of Inglewood and hence on the Inglewood Unified School District. Alternative D expands the airport complex to the east, and although the I-405 Freeway acts somewhat as a barrier with respect to direct impacts in Inglewood, there is the potential for indirect impacts that are difficult to quantify and therefore are either not addressed or only briefly addressed in the SEIS/EIR. Some examples are:

a. Freeway Avoidance Traffic.

Most of the freeway and freeway access mitigation measures will need to be the subject of further analysis as Caltrans Project Study Reports are prepared and more detailed designs are formulated. There is no assurance that desired freeway levels of service will be achieved when both project and cumulative impacts are considered. Under such conditions, "freeway avoidance" traffic could impact local streets and some of that freeway avoidance traffic will include airport trips (primarily employee and service related trips rather than air passenger trips). Actual conditions on the Inglewood street system could therefore be worse than portrayed in the SEIS/EIR. Ideally, some provision should be made for monitoring traffic conditions to determine the magnitude of such trips, and to establish some form of "second tier" list of improvements for locations that may be impacted in this manner with trigger points for implementing improvements.

b. Construction.

The SEIS/EIR discusses construction traffic routing as a mitigation measure for project construction. The Inglewood Unified School District should be involved in this process, and to the extent possible, include the Inglewood Unified School District in reviewing construction traffic routing to ensure that minimum impacts occur to schools, particularly those in close proximity to the airport.

c. Phasing.

The phasing of transportation improvements is an important issue. Some discussion is given in the SEIS/EIR based on a conceptual phasing plan for the Master Plan. That phasing will be a complex undertaking, and should be accompanied by a detailed disclosure of impacts and mitigation measures for each phase as the details of the phasing plan emerge. Inglewood's close proximity to the airport makes it vulnerable to any situation in which unanticipated traffic impacts of a particular phase causes problems on the local street system. Such impacts could well exceed those identified for the 2008 and 2015 time frames in the SEIS/EIR.

PART SIX

THE ENROLLMENT IMPACT ANALYSIS IS MISLEADING

The SEIS/EIR discusses the impact of Alternative D on enrollment as follows:

“Due to productivity increases (i.e., the production of more economic output per worker), Alternative D would result in a decrease of approximately 2,657 on-airport employees within the schools study area by 2015. As each on-airport employee is assumed to represent one household, the number of on-airport employee households within the schools study area would, therefore, decline by approximately 2,657.” (SEIS/EIR, *Schools*, Section 4.27, p. 4-764.)

As to student enrollment in the Inglewood Unified School District, the SEIS/EIR states:

“... [T]he maximum enrollment decline estimate ... between 1996/1997 and 2015 would be 225 students in the Inglewood Unified School District.” (SEIS/EIR, *Schools*, Section 4.27, p. 4-765.)

Thus, the SEIS/EIR concludes, this decrease in student enrollment as a result of Alternative D will not result in any impact to the Inglewood Unified School District. This conclusion is wrong.

The use of the 1996/1997 year as a baseline for the purposes of determining the impact on student enrollment is not justified and renders an artificially low result. Since 1996, student enrollment in Inglewood schools has increased by over 800 students. (See, e.g., Original EIS/EIR Response Exhibit 14 to Response, page 58.) Accordingly, is the actual effect of Alternative D upon student enrollment a decrease in over 1,000 students? It is impossible to conclude based upon the very brief analysis of Inglewood Unified School District enrollment in the SEIS/EIR, but this does appear to be the logical conclusion.

Whether the decrease in students is only 225 or in reality over 1,000, the impact on the Inglewood Unified School District will be substantial. The Inglewood Unified School District relies almost exclusively on Average Daily Attendance for its revenue. A loss of 225 students may mean the loss of over \$1,050,000 per year in student generated revenue. Should the decrease in student enrollment actually be over 1,000, it would mean the loss of over \$4,700,000 in student attendance generated annual revenue.

Either of these impacts would translate into significant impacts upon budgeting, employment, maintenance and operations within the Inglewood Unified School District, *must* be studied further, and mitigation measures must be developed to address these impacts.

PART SEVEN

THE SUBSTANTIAL SHIFT IN PROJECT OBJECTIVES REQUIRES LAWA TO EXAMINE AN ADEQUATE RANGE OF PROJECT ALTERNATIVES

Following the events of September 11th terrorist attacks, the basic objectives of the project have significantly shifted to an emphasis on security and safety over expansion. Several statements have been attributed to Mayor Hahn to this effect. However, Mayor Hahn's new objectives are only addressed in one alternative, Alternative D, the only alternative admittedly focused on enhanced safety and security measures.

The 1998 amendments to the CEQA Guidelines emphasized the importance of a clearly written statement of objectives. The following language was added for the requirements of the "project description,"

"A clearly written statement of objectives will help the lead agency develop a reasonable range of alternatives to evaluate in the EIR and will aid the decision makers in preparing findings or a statement of overriding considerations, if necessary. The statement of objectives should include the underlying purpose of the project."
(14 *California Code of Regulations* 15124(b).)

A discussion of this section by the Governor's Office of Planning and Research provides further insight into this amendment - "Clear project objectives simplify the selection process by providing a standard against which to measure possible alternatives."

The standard by which to judge the range of alternatives required in an EIR is governed by the "rule of reason." 14 *California Code of Regulations* 15126.6(a); *Citizens of Goleta Valley v. Board of Supervisors* (1990) 52 Cal.3d 553, 565. In this case, LAWA completely changed its focus and objectives for the LAX project, yet only set forth one alternative in the SEIS/EIR to address these objectives. By only addressing one alternative, LAWA has effectively limited the public from meaningful public participation and informed decision making. It precludes the option of selecting a project that addresses the safety and security concerns of LAWA with less of an accompanying environmental justice impact. The notable lack of alternatives does not permit a reasoned choice and does not withstand the CEQA's "rule of reason."

When LAWA presented a 180 degree shift in its basic and central objectives, LAWA was required to comply with CEQA by discussing a reasonable range of alternatives. LAWA's failure to do so is fatal to the SEIS/EIR.

PART EIGHT

THE EIS/EIR VIOLATES CEQA READABILITY REQUIREMENTS

California *Public Resources Code* § 21003 states, in pertinent part:

“The Legislature further finds and declares that it is the policy of the state that:

“(b) Documents prepared pursuant to this division be organized and written in a manner that will be meaningful and useful to decision makers and to the public. . .

“(f) All persons and public agencies involved in the environmental review process be responsible for carrying out the process in the most efficient, expeditious manner in order to conserve the available financial, governmental, physical and social resources with the objective that those resources may be better applied toward the mitigation of actual significant effects on the environment.”

Both the Original EIS/EIR and the SEIS/EIR violate this Code section.

a. Original EIS/EIR.

The Original EIS/EIR is inaccessible. It is 12,000 pages long and costs thousands of dollars to purchase. The CD version, although less expensive, is only accessible to people with computers. Many poorer residents of the most highly impacted areas do not have that technology. Additionally, the CD version contains many glitches, so entire sections are impossible to read or print. (See, e.g., EIS/EIR, CD Version *Technical Report 4*.)

Second, the Original EIS/EIR is so poorly organized that it is nearly impossible to find all of the pertinent information regarding a topic. Analysis regarding a particular topic is often spread among numerous sections of the “main document.” Several of the so-called “technical reports” contain substantive narrative that is not reflected in the report itself. The “appendices” often contain other important information. The document itself provides no logical explanation as to why its contents are distributed in this manner.

For instance, as expected, the *Noise* section of the Original EIS/EIR contains information regarding the noise impacts of LAX expansion upon Inglewood Unified School District schools. However, the *Noise Technical Report*, thousands of pages later, contains crucial noise impact information that is entirely absent from the *Noise* section of the main document. In addition, the *Noise Technical Report* is not contained on the CD entitled “Technical Reports”. Instead, it is on the “Appendices” CD, and is actually Appendix “D”. The reason for this is entirely unclear.

The *Land Use* section, a thousand pages from the *Noise* section and several thousand pages from the *Noise Technical Report*, essentially states that LAWA will not mitigate noise

impacts identified in the *Noise* section. (EIS/EIR, *Land Use*, Section 4.2, pp. 4-95, 4-96.) These few, critical sentences are not contained in the *Noise* section of the main document, nor the *Noise Technical Report*. This illogical placement of this crucial language suggests an intentional decision to obscure information that would raise "red flags" in respondents.

b. Addition of Supplement to the EIS/EIR.

The SEIS/EIR contains many of the same problems of the Original EIS/EIR. It is thousands of pages long and costs over a thousand dollars to purchase. Consistent with the Original EIS/EIR, the various *Supplemental Noise Technical Reports* and the *Environmental Justice Technical Report* are contained in the "Appendices" rather than with the "Technical Reports," as would make sense. Although the CD version of the document is less expensive, it is not accessible to those impacted citizens of Inglewood who do not have access to a computer and are not trained to utilize the complex programs required to read from the CDs.

In total, the EIS/EIR violate CEQA readability requirements, and are inaccessible to a significant portion of the population impacted by the project that is the subject of the EIS/EIR.

CONCLUSION

The individual and cumulative impacts of the EIS/EIR, including Alternative D, upon the education, health and safety of its students are of substantial concern to the Inglewood Unified School District. By law, LAWA must adequately consider and mitigate these impacts in its EIS/EIR. It fails to do so.

The EIS/EIR fails to adequately analyze the environmental justice, noise, health, pollution, traffic and enrollment impacts of the proposed project upon the Inglewood Unified School District. The EIS/EIR fails to propose adequate mitigation measures for these impacts. Furthermore, the EIS/EIR analysis of the cumulative impacts of the LAX expansion upon the Inglewood Unified School District is inadequate, both due to its own insufficiency and due to the inadequacy of its analyses of the underlying impacts.

For the foregoing reasons, the Inglewood Unified School District respectfully requests that LAWA revise the EIS/EIR to include alternative projects, further impact analysis and site specific mitigation information and proposals regarding the impacts on the Inglewood Unified School District.

Presidential Documents

Title 3—

Executive Order 12898 of February 11, 1994

The President

Federal Actions To Address Environmental Justice in Minority Populations and Low-Income Populations

By the authority vested in me as President by the Constitution and the laws of the United States of America, it is hereby ordered as follows:

Section 1-1. Implementation.

1-101. *Agency Responsibilities.* To the greatest extent practicable and permitted by law, and consistent with the principles set forth in the report on the National Performance Review, each Federal agency shall make achieving environmental justice part of its mission by identifying and addressing, as appropriate, disproportionately high and adverse human health or environmental effects of its programs, policies, and activities on minority populations and low-income populations in the United States and its territories and possessions, the District of Columbia, the Commonwealth of Puerto Rico, and the Commonwealth of the Mariana Islands.

1-102. *Creation of an Interagency Working Group on Environmental Justice.*

(a) Within 3 months of the date of this order, the Administrator of the Environmental Protection Agency ("Administrator") or the Administrator's designee shall convene an interagency Federal Working Group on Environmental Justice ("Working Group"). The Working Group shall comprise the heads of the following executive agencies and offices, or their designees: (a) Department of Defense; (b) Department of Health and Human Services; (c) Department of Housing and Urban Development; (d) Department of Labor; (e) Department of Agriculture; (f) Department of Transportation; (g) Department of Justice; (h) Department of the Interior; (i) Department of Commerce; (j) Department of Energy; (k) Environmental Protection Agency; (l) Office of Management and Budget; (m) Office of Science and Technology Policy; (n) Office of the Deputy Assistant to the President for Environmental Policy; (o) Office of the Assistant to the President for Domestic Policy; (p) National Economic Council; (q) Council of Economic Advisers; and (r) such other Government officials as the President may designate. The Working Group shall report to the President through the Deputy Assistant to the President for Environmental Policy and the Assistant to the President for Domestic Policy.

(b) The Working Group shall: (1) provide guidance to Federal agencies on criteria for identifying disproportionately high and adverse human health or environmental effects on minority populations and low-income populations;

(2) coordinate with, provide guidance to, and serve as a clearinghouse for, each Federal agency as it develops an environmental justice strategy as required by section 1-103 of this order, in order to ensure that the administration, interpretation and enforcement of programs, activities and policies are undertaken in a consistent manner;

(3) assist in coordinating research by, and stimulating cooperation among, the Environmental Protection Agency, the Department of Health and Human Services, the Department of Housing and Urban Development, and other agencies conducting research or other activities in accordance with section 3-3 of this order;

(4) assist in coordinating data collection, required by this order;

(5) examine existing data and studies on environmental justice;

(6) hold public meetings as required in section 5-502(d) of this order; and

(7) develop interagency model projects on environmental justice that evidence cooperation among Federal agencies.

1-103. *Development of Agency Strategies.* (a) Except as provided in section 6-605 of this order, each Federal agency shall develop an agency-wide environmental justice strategy, as set forth in subsections (b)-(e) of this section that identifies and addresses disproportionately high and adverse human health or environmental effects of its programs, policies, and activities on minority populations and low-income populations. The environmental justice strategy shall list programs, policies, planning and public participation processes, enforcement, and/or rulemakings related to human health or the environment that should be revised to, at a minimum: (1) promote enforcement of all health and environmental statutes in areas with minority populations and low-income populations; (2) ensure greater public participation; (3) improve research and data collection relating to the health of and environment of minority populations and low-income populations; and (4) identify differential patterns of consumption of natural resources among minority populations and low-income populations. In addition, the environmental justice strategy shall include, where appropriate, a timetable for undertaking identified revisions and consideration of economic and social implications of the revisions.

(b) Within 4 months of the date of this order, each Federal agency shall identify an internal administrative process for developing its environmental justice strategy, and shall inform the Working Group of the process.

(c) Within 6 months of the date of this order, each Federal agency shall provide the Working Group with an outline of its proposed environmental justice strategy.

(d) Within 10 months of the date of this order, each Federal agency shall provide the Working Group with its proposed environmental justice strategy.

(e) Within 12 months of the date of this order, each Federal agency shall finalize its environmental justice strategy and provide a copy and written description of its strategy to the Working Group. During the 12 month period from the date of this order, each Federal agency, as part of its environmental justice strategy, shall identify several specific projects that can be promptly undertaken to address particular concerns identified during the development of the proposed environmental justice strategy, and a schedule for implementing those projects.

(f) Within 24 months of the date of this order, each Federal agency shall report to the Working Group on its progress in implementing its agency-wide environmental justice strategy.

(g) Federal agencies shall provide additional periodic reports to the Working Group as requested by the Working Group.

1-104. *Reports to the President.* Within 14 months of the date of this order, the Working Group shall submit to the President, through the Office of the Deputy Assistant to the President for Environmental Policy and the Office of the Assistant to the President for Domestic Policy, a report that describes the implementation of this order, and includes the final environmental justice strategies described in section 1-103(e) of this order.

Sec. 2-2. *Federal Agency Responsibilities for Federal Programs.* Each Federal agency shall conduct its programs, policies, and activities that substantially affect human health or the environment, in a manner that ensures that such programs, policies, and activities do not have the effect of excluding persons (including populations) from participation in, denying persons (including populations) the benefits of, or subjecting persons (including populations) to discrimination under, such programs, policies, and activities, because of their race, color, or national origin.

Sec. 3-3. Research, Data Collection, and Analysis.

3-301. Human Health and Environmental Research and Analysis. (a) Environmental human health research, whenever practicable and appropriate, shall include diverse segments of the population in epidemiological and clinical studies, including segments at high risk from environmental hazards, such as minority populations, low-income populations and workers who may be exposed to substantial environmental hazards.

(b) Environmental human health analyses, whenever practicable and appropriate, shall identify multiple and cumulative exposures.

(c) Federal agencies shall provide minority populations and low-income populations the opportunity to comment on the development and design of research strategies undertaken pursuant to this order.

3-302. Human Health and Environmental Data Collection and Analysis. To the extent permitted by existing law, including the Privacy Act, as amended (5 U.S.C. section 552a): (a) each Federal agency, whenever practicable and appropriate, shall collect, maintain, and analyze information assessing and comparing environmental and human health risks borne by populations identified by race, national origin, or income. To the extent practical and appropriate, Federal agencies shall use this information to determine whether their programs, policies, and activities have disproportionately high and adverse human health or environmental effects on minority populations and low-income populations;

(b) In connection with the development and implementation of agency strategies in section 1-103 of this order, each Federal agency, whenever practicable and appropriate, shall collect, maintain and analyze information on the race, national origin, income level, and other readily accessible and appropriate information for areas surrounding facilities or sites expected to have a substantial environmental, human health, or economic effect on the surrounding populations, when such facilities or sites become the subject of a substantial Federal environmental administrative or judicial action. Such information shall be made available to the public, unless prohibited by law; and

(c) Each Federal agency, whenever practicable and appropriate, shall collect, maintain, and analyze information on the race, national origin, income level, and other readily accessible and appropriate information for areas surrounding Federal facilities that are: (1) subject to the reporting requirements under the Emergency Planning and Community Right-to-Know Act, 42 U.S.C. section 11001-11050 as mandated in Executive Order No. 12856; and (2) expected to have a substantial environmental, human health, or economic effect on surrounding populations. Such information shall be made available to the public, unless prohibited by law.

(d) In carrying out the responsibilities in this section, each Federal agency, whenever practicable and appropriate, shall share information and eliminate unnecessary duplication of efforts through the use of existing data systems and cooperative agreements among Federal agencies and with State, local, and tribal governments.

Sec. 4-4. Subsistence Consumption of Fish and Wildlife.

4-401. Consumption Patterns. In order to assist in identifying the need for ensuring protection of populations with differential patterns of subsistence consumption of fish and wildlife, Federal agencies, whenever practicable and appropriate, shall collect, maintain, and analyze information on the consumption patterns of populations who principally rely on fish and/or wildlife for subsistence. Federal agencies shall communicate to the public the risks of those consumption patterns.

4-402. Guidance. Federal agencies, whenever practicable and appropriate, shall work in a coordinated manner to publish guidance reflecting the latest scientific information available concerning methods for evaluating the human health risks associated with the consumption of pollutant-bearing fish or

wildlife. Agencies shall consider such guidance in developing their policies and rules.

Sec. 5-5. Public Participation and Access to Information. (a) The public may submit recommendations to Federal agencies relating to the incorporation of environmental justice principles into Federal agency programs or policies. Each Federal agency shall convey such recommendations to the Working Group.

(b) Each Federal agency may, whenever practicable and appropriate, translate crucial public documents, notices, and hearings relating to human health or the environment for limited English speaking populations.

(c) Each Federal agency shall work to ensure that public documents, notices, and hearings relating to human health or the environment are concise, understandable, and readily accessible to the public.

(d) The Working Group shall hold public meetings, as appropriate, for the purpose of fact-finding, receiving public comments, and conducting inquiries concerning environmental justice. The Working Group shall prepare for public review a summary of the comments and recommendations discussed at the public meetings.

Sec. 6-6. General Provisions.

6-601. Responsibility for Agency Implementation. The head of each Federal agency shall be responsible for ensuring compliance with this order. Each Federal agency shall conduct internal reviews and take such other steps as may be necessary to monitor compliance with this order.

6-602. Executive Order No. 12250. This Executive order is intended to supplement but not supersede Executive Order No. 12250, which requires consistent and effective implementation of various laws prohibiting discriminatory practices in programs receiving Federal financial assistance. Nothing herein shall limit the effect or mandate of Executive Order No. 12250.

6-603. Executive Order No. 12875. This Executive order is not intended to limit the effect or mandate of Executive Order No. 12875.

6-604. Scope. For purposes of this order, Federal agency means any agency on the Working Group, and such other agencies as may be designated by the President, that conducts any Federal program or activity that substantially affects human health or the environment. Independent agencies are requested to comply with the provisions of this order.

6-605. Petitions for Exemptions. The head of a Federal agency may petition the President for an exemption from the requirements of this order on the grounds that all or some of the petitioning agency's programs or activities should not be subject to the requirements of this order.

6-606. Native American Programs. Each Federal agency responsibility set forth under this order shall apply equally to Native American programs. In addition, the Department of the Interior, in coordination with the Working Group, and, after consultation with tribal leaders, shall coordinate steps to be taken pursuant to this order that address Federally-recognized Indian Tribes.

6-607. Costs. Unless otherwise provided by law, Federal agencies shall assume the financial costs of complying with this order.

6-608. General. Federal agencies shall implement this order consistent with, and to the extent permitted by, existing law.

6-609. Judicial Review. This order is intended only to improve the internal management of the executive branch and is not intended to, nor does it create any right, benefit, or trust responsibility, substantive or procedural, enforceable at law or equity by a party against the United States, its agencies, its officers, or any person. This order shall not be construed to create any right to judicial review involving the compliance or noncompliance

of the United States, its agencies, its officers, or any other person with this order.

15. SUPPLEMENTARY NOTES This study was performed in cooperation with the U.S. Department of Transportation, Federal Highway Administration.					
16. ABSTRACT <p>There is a significant acoustical difference between State and Federal rules governing implementation of noise abatement programs in schools impacted by freeway noise. The magnitude of that difference suggests the rules may have been based upon empirically weak grounds. This study of third and sixth grades of 15 elementary schools in the Los Angeles Unified School District indicates that California's rule is more accurate than is the Federal rule in predicting the effects of noise on reading achievement.</p> <p>Based upon this study and another independent study, a revision of the existing rule is recommended. The design criterion for traffic noise levels inside classrooms should be $L_{eq} = 58$ dB C-weighted. This criterion level is approximately 7 dB less than the current Federal standard and about 6 dB higher than the California standard.</p> <p>Because of the apparent synergistic effects of community and classroom noise levels on academic achievement, in order for the above classroom noise limit to be effective in preventing degradation of achievement from noise, efforts will be required to contain community noise levels so as not to exceed $L_1 = 65$ dBA.</p>

NOTICES

Funding for this study was provided by the Federal Highway Administration through the California Department of Transportation (I.A.A. 19-7165) and by the California Department of Health Services. Assistance of Juanita Oñate and Robert Heald in collection and analysis of the classroom data, of the Environmental Investigation Section, District 7, of Caltrans in collecting the community noise and air quality data, and of Dee Nichols for typing is acknowledged with gratitude.

The contents of this report reflect the views of the Office of Noise Control of the California Department of Health Services which is responsible for the facts and the accuracy of the data presented herein. The contents do not necessarily reflect the official views or policies of the State of California or the Federal Highway Administration. While this report contains useful information and advances the state of knowledge concerning the relationship between classroom noise and academic achievement, the report may not constitute an adequate basis for changing either the California or Federal regulations regarding acceptable noise levels in classrooms at this time. This report does not constitute a standard, specification, or regulation.

Neither the State of California nor the United States Government endorse products or manufacturers. Trade or manufacturers' names appear herein only because they are considered essential to the objective of this document.

Final Report

Effects of Noise on Academic Achievement and Classroom Behavior

Jerome S. Lukas, Russell B. DuPree, and Jack W. Swing

Introduction

Some studies have suggested that noise from external sources affects teachers' and childrens' behavior and childrens' achievement in school. For example, Crook and Langdon,¹ in a study of schools exposed to aircraft noise, found that teachers typically paused in their discourses when peak noise levels reached 80 dBA, even though voice levels were raised to compensate for the increased noise levels. With respect to academics, Bronzaft and McCarthy² found that children exposed to elevated train noise at peak levels of about 90 dBA were three to four months behind their schoolmates in quieter classrooms in reading. Cohen, et al³ reported a similar result in children exposed to aircraft noise. An unpublished preliminary study by the California Department of Health Services obtained results similar to those of Bronzaft and McCarthy and Cohen, et al. Our study suggested that reading achievement of third and sixth graders in "noisy" schools⁴ was poorer than that of socioeconomically comparable students in "quiet" schools.

The above study raised more questions than it answered. For example, because school noise levels were unknown, we assumed that all classrooms in "noisy" schools were equally noisy, while in "quiet" schools they were equally quiet. In addition, we assumed that community noise levels were comparable. Perhaps proximity to freeways was correlated with high levels of other pollutants—lead, carbon monoxide, nitrous oxide, etc., and these may explain the difference in reading ability. Or, more simply, our results may have been due to an unique combination of schools.

In contrast to the characteristics of noise that might be expected in schools adjacent to freeways, in the other studies different levels, durations, periodicities, and sources of noise were observed. Hence, the results may not be applicable to the freeway and traffic situations found in cities.

This lack of scientific data is in part responsible for the existence of two different rules governing implementation of a noise abatement program for schools adjacent to freeways. California law states that noise abatement must occur when the noise level inside the classroom exceeds 50 dBA. In contrast, the federal program becomes operational when the noise level reaches an $L_{10}=55$ dBA. This is equivalent to about 63 dBA⁴ under California's rule. Thus, there is a clear need to determine which of these rules is more appropriate.

The study described below was designed to examine the extent to which exposure to freeway noise affects children in school and to determine a criterion noise level for a school noise abatement program. The effects investigated were both behavioral and academic. We tentatively hypothesized that there would be correlations between external noise levels, behavioral effects,

1. A list of references and technical notes in numerical order is appended.

⁴"Noisy" schools were defined as schools adjacent to freeways that qualified for noise abatement work by State criteria (see below), while "quiet" schools were those nearest each "noisy" school (usually within one-half mile) but further from the freeway.

and academic achievement and that degradation of classroom behavior may explain, at least in part, reductions in academic achievement.

In addition, measures of air quality were obtained for eight of the schools under study and were selected according to (a) their proximity to the freeway, (b) their location with respect to the freeway and prevailing winds, and (c) the topography of the greater Los Angeles area. These data were used to determine roughly whether the schools studied were comparable with respect to air quality.

Method

A. Selection of Schools

The so-called "noisy" schools were selected because they were located adjacent to freeways, and because measurements by the California Department of Transportation indicated that peak noise levels in the worst classrooms exceeded 60 dBA. In addition, corrective noise abatement work was scheduled after completion of our study. It should be noted that CalTrans' noise abatement program began long before the study. Thus, we were unable to study the noisiest schools (peak levels above 80 dBA) and if we had, perhaps the effects would have spanned a greater range than those to be shown subsequently.

Two criteria were used to select the quiet schools. In general, we selected the school closest to each noisy school, but the quiet school was further from the freeway. It was assumed on the basis of the preliminary study mentioned above, that this technique would result in socioeconomically comparable "noisy" and "quiet" schools. The second criterion involved use of the teachers' estimates of parental employment to assure greater comparability. These estimates of parental employment were obtained as follows. Each year the State Department of Education requires that third and sixth grade students be administered standard tests in reading and mathematics. This test is the California Assessment Program, referred to hereafter as the CAP. The teacher fills out an information form for each child which includes a categorized question about parental occupation. The categories are: 0—Unskilled or Welfare; 1—Skilled and Semi-skilled; 2—Semi-professionals, Clerks, Sales and Technicians; 3—Executives, Professionals, and Managers. The Socioeconomic Index (S.E.I.) for a school is the average of the students tested.

This index was a rough estimate at best. Nevertheless, it was all that was available and was used for the initial selection of schools. Subsequently, more precise data were made available from several sources. These were used to develop other indicators of socioeconomic status that are shown in Table 1. These indicators were calculated from the "block data" of the U.S. Census, some data provided by the Los Angeles City Planning Department, and by a private survey company. Details of the procedure for estimating the socioeconomic variables can be found in Appendix A.

Three matching quiet schools are missing in Table I. Several reasons accounted for this. One school principal refused to participate in the study because his school was not noisy. Another school was dropped when after driving through the area we found relatively few homes in an area devoted to heavy commerce which is serviced frequently by large trucks and trailers. Unpredictable delays in our schedule were caused by school holidays, and non-academic preparations for festive events such as Mothers' and Fathers' Days, Halloween, Valentine's Day, or teacher training and parent-teacher conference days. Finally, contractual and financial constraints required completion of our classroom observations in the 1978-79 school year.

S.E.I.: Socioeconomic Index. An average of teachers' rankings of parental occupation, where 0 is welfare or unskilled laborer, 1 is skilled or semi-skilled, 2 is semi-professionals, clerks, sales and technicians, and 3 is executives, professionals, and managers. To indicate variability in the Index, the top number is for 3rd grades in 1974/75, and the bottom number is for the same grades in 1975/76. A dash indicates data were not available.

Median Family Income: Estimated as described in Appendix A.

% Poverty: Percentage of families in poverty, based on average household size of 3.67 individuals - the U.S. Average. This corresponds to an income level of \$6,180, according to the U.S. Bureau of the Census for the year 1978. See Appendix A.

% Unemp.: Percentage of employable persons who are unemployed. See Appendix A.

% Black, Hispanic, and White Students: Another category, "Asian/Pacific Islander", was excluded. The percentages should add to 100%, and the difference between 100% and the sum will account for Asians/Pacific Islanders because the number of American Indians or Alaskan natives was, at most, 6 or 1.4% at school 6893. Typically, there were no or only a fraction of a percent of American Indians or Alaskan natives at these schools. Data provided by the Los Angeles Unified School District.

% N.E.S.: Non-English Speaking. The percentage of children in the 3rd and 6th grades who did not speak English with native-born fluency. In most schools these children were recent immigrants of Hispanic origin. No. 1 refers to children of "limited" ability in English, and No. 2 are non-English speaking.

No. of Students: No. in school/no. tested in 3rd 6th grades.

Comparison of the indicators in Table I suggests that our matching of schools produced roughly comparable sets of noisy and quiet schools. This assessment of comparability is correct if one accepts differences in racial composition of up to 10 percentage points or differences of more than \$1,000 in Median Family Income as not being significant. For example, in schools 9251 and 6174, the noisy school had about 10 percent more Blacks and fewer Hispanics (about 8 percentage points), and the latter school's families had \$1,000 more income yearly than did the parents of school 9251, although the unemployment rates were almost equal. Note also that despite the higher Median Family Income for school 6174, this school had a larger percentage of families in poverty than did school 9251.

Schools 7651 and 9004 were very dissimilar with respect to racial composition. These schools were initially matched on the basis of S.E.I. alone, without regard to location. In subsequent analyses, these schools were not paired.

In the aggregate, the various socioeconomic indicators suggest that the schools studied might be called minority schools because of the disproportionately large numbers of Black or Hispanic students. For purposes of comparison, the distribution of racial and ethnic groups in all of the Los Angeles Unified School District's elementary schools in the Fall of 1978 follows: American Indian or Alaskan Native, 0.5%; Black, 22.7%; Asian or Pacific Islander, 6.4%; of Hispanic origin, 46.3%; White, 24.9%. Because of the relatively high percentages of unemployed and families in poverty, as shown in Table I, our group of schools might also be called poor.

It may be concluded that the results of the study are applicable to schools of racial, ethnic, and economic comparison similar to those shown. The results may not be applicable to schools with much larger percentages of White or Asian students.

A final caution about interpretation of the Non-English-Speaking (N.E.S.) category is warranted. The decision to test or not to test a student with limited skills in English is left to the school staff. In some cases, teachers or principals may be interested in how well some or all the children are doing academically and may require tests of all, regardless of language limitations. Others may think that because some children are so poor in English, testing would be of little value, and only "Category 1" children are tested. The test score rosters contain information only about children who are tested. Thus, they reflect teacher selection of students who should be tested. The numbers should not be interpreted as reflecting relative fluency in English in the various schools. For purposes of analysis of the academic data, we have treated the children who spoke English fluently separately from those of less fluency as defined by N.E.S. Categories 1 and 2.

1. Schools and Classrooms Excluded

As a rule, we excluded schools that were part of a newly-established bussing program and classrooms that did not have full-time teachers. The behavioral data (but not achievement or noise data) from school 7214 were excluded from analysis because it was the first school studied (it was studied in the 1977 school year) and was used to test and refine our procedures. It is unfortunate that this particular school was chosen for this purpose, because it is the nearest match for school 8501.

Almost all of the principals and teachers were most cooperative, although some were suspicious initially or had reservations about the purposes of the study. Because participation was voluntary, we did not coerce teachers; rather, we used persuasion. Generally we met first with the principals, explained the program, obtained information regarding the number and locations of the third and sixth grades, teachers' names, and the number of children in the school. At this meeting we also set up a tentative schedule for our work in the school and for meeting with the teachers involved. Prior to meeting with the teachers, they were sent a brief description of the study (see Appendix B). At the meeting, this description was elaborated,

discussed, and all questions were answered. Despite these efforts, a few teachers refused to participate in the study. Some refused at the meeting, a few upon our entry into the classrooms to begin work, and some became ill on their scheduled days. If we could reschedule to accommodate the illness, we did; if not and a substitute teacher was used, the data were excluded. We also excluded data from classrooms that were almost completely out-of-control, or if most of the day(s) was spent at rehearsals, preparation for dances, preparing Valentines, Christmas decorations, etc. Occasionally the equipment malfunctioned.

Table II lists the number of classrooms and the number of days during which we obtained usable data. In some cases, usable data were obtained for a portion of the day—such as during a period devoted to mathematics. Such instances are not discriminated in the table.

It will be noted that in some classrooms we obtained data during more than three days. Typically, this occurred when a teacher of another classroom decided not to participate or became ill. Rather than wasting a day, we extended the observation period for a given classroom, if that teacher permitted. It was thought this technique would result in more accurate estimates of classroom behavior, particularly as they relate to noise levels.

2. Classrooms Combined

As will be shown subsequently, children who were not fluent in English consistently performed less well on the achievement tests than did children fluent in English. Thus, the achievement data of the two groups of children had to be analyzed separately.

In the classrooms studied, the numbers of English fluent and non-fluent children varied with the language skills of the teacher, particularly in schools with large Hispanic populations. This student distribution problem became apparent after we had observed most of the classrooms in the second school and became very clear after we had obtained the achievement test results that identified the non-English speaking students in each classroom. The reason is that the number and location of Spanish-speaking teachers does not correspond to the number of Spanish-speaking students. Thus, English-speaking students typically are taught by English-speaking teachers, whereas bilingual teachers have predominantly English-weak and non-English-speaking students.

For obvious reasons, it is invalid to perform statistical comparisons based upon samples of one or two students. Thus, we were forced to combine some data. Data from two classrooms were combined if their exposures to external noise sources were either found to be or were expected to be comparable or within 2 dB; in most cases these were adjacent classrooms. All of the classrooms, either in combination or singly, had an N of 5 or more (mean=17.2, σ =7.2). Although an N of 5 is admittedly small, the acoustics of a particular school's location or construction would not permit combination of more classrooms as being representative of a particular noise exposure. In the few cases where student numbers were less than 2 and where classroom noise levels were not comparable, the data were deleted.

B. Noise in the Communities

The fact that children are exposed to noise in their non-school environments as well as in their schools is indisputable. The problem for the study described herein is to discern the extent to which noise levels in the schools affect childrens' academic achievement independently of their non-school exposures. That achievement might be related to noise exposures in the non-school environment was suggested by Cohen, Glass and Singer⁵. They examined the reading abilities of socioeconomically comparable children attending

the same schools and residing in the same New York apartment building. They found that children living on the noisier lower floors with closer proximity to a freeway had reading levels lower than those children residing on the higher floors.

1. Method

The Noise Monitoring Survey, Class II, as developed and described by Wyle Research,⁶ was used. It is described briefly below and Appendix C describes the survey techniques in greater detail.

Students were assigned to a particular school if they lived within a distance of 1/4 to 1/2 mile of the school. Using maps of these "feeder areas" for each school, the area was subdivided into five or six locations that would estimate community noise levels considering local traffic patterns, noise sources, and the pattern of residences. These are called "spatial sampling units". Once the spatial sampling units for a given school were localized, the principal or a representative of the community was asked to provide the names, addresses, and telephone numbers of volunteers in each unit who would permit us to set up the equipment at their homes. The research group subsequently met with the volunteers, explained the study and what was expected of them, described the equipment, and arranged for an equipment set-up date. Volunteers were paid \$5.00 for each day the equipment was at their homes. Because volunteers were used, the sites were not always where we would have wished. They may have been, for example, at most a block from the ideal location. Nevertheless, the sites are believed to be representative of the sampling units.

Microphone masts were attached to the plumbing vent pipes atop the homes, and the microphones were located at the top of the mast about 6 feet above the roof. Every effort was made to prevent shielding of microphones by roof peaks and chimneys. Roofs were used to prevent shielding by adjacent buildings and to preclude vandalism.

At each sampling site, a Type 1945 Gen Rad Community Noise Level Monitor provided samples during most of the 24-hour day. A copy of a completed Community Noise Survey Data Sheet is provided as Figure 10 in Appendix C. It shows the sampling periods used throughout the day and night and the noise level indices that were recorded.

In addition to the sampling procedure with the Gen Rad 1945 at fixed sites, a Bolt Beranek and Newman Model 614 Portable Noise Monitor or a Gen Rad 1945 were used at selected "roving sites". Roving sites—two or three at each school—were used to provide better coverage of the sampling units, to corroborate data obtained at the fixed sites or, in lieu of fixed sites, if volunteers were unavailable in a particular sampling unit. Sampling durations (typically 1/2 hour) at the roving sites were necessarily shorter than those shown on the Community Noise Survey Data Sheet, but did occur within the time periods shown.

2. Community Noise Levels⁷

The community noise levels are described and discussed here rather than in the Results section because they are relevant to the comparability of the schools and are similar to socioeconomic factors.

Shown in Table III are several measures of noise levels in communities providing children to the schools. School 9251 may be compared with 6174 and 9004 as was discussed on page 3, while the four largely Hispanic schools are shown at the bottom of the table.

*L₁, L₁₀, L₉₉ and L_{NP} are averages over all sites, both fixed and roving (see Appendix C), throughout each community. The measurements occurred during Morning Rush Hours, Midday, Evening and Night.

L_{NP} for each measurement period = L_{eq} + (L₁₀ - L₉₀), and

L_{eq 24} = Logarithmic averages of levels measured during the four periods.

By and large, the differences between the "noisy" and "quiet" neighborhoods are neither consistent nor remarkably large. Indeed, some so-called quiet neighborhoods are noisier than their adjacent noisy neighborhoods (e.g., schools 9251 and 6174). Maps and observation of the areas indicate that local traffic patterns and the types of traffic are the cause. For example, although school 9251 is adjacent to a freeway, there is almost no truck traffic through its feeder area. In contrast, feeder areas for schools 6174 and 9004 are intersected by one or two major thoroughfares carrying frequent automobile and truck traffic to and from the freeway. Occasionally this traffic may bypass major intersections through residential streets. In addition, the areas are economically poor, so that many old cars in poor condition and with inadequate mufflers travel the streets. It is reasonable to expect that higher unemployment and/or poverty levels are correlated with relatively higher frequencies of decrepit automobiles; hence, there may be some correlation between the economic indices and community noise levels even in poor areas that are not adjacent to freeways.

On the average, the L_{99} appears to be the best discriminator between noisy and quiet neighborhoods; noisy areas having an average $L_{99} = 53.4$ dBA, while quiet ones average 47.5 dBA. The L_{99} may be thought of as the background, or residual, noise level obtained when the sources of noise are absent or remote from the monitoring sites.

In general, both the "noisy" and "quiet" feeder areas are shown to be relatively noisy. Only in the middle of the night at some monitoring sites in certain quiet areas did the minimum levels go down to 35 dBA or so. Compilations of noise levels at the different measurement times are shown in Appendix D; see also Figure 16, Appendix C. Because studies relating academic achievement and environmental levels are few and inconclusive, the levels shown here may be spurious. Statistical analyses described subsequently suggest the relationship between the various community noise levels and achievement.

3. Other Pollutants in School Areas⁸

The results presented in Figure 12 of Appendix C suggest that the concentrations of lead and carbon monoxide* are not related to the proximity of the school to the freeway; rather, the concentrations appear to be relatively uniform among the schools we studied in the Los Angeles Basin. It may be concluded that the children in the schools studied were exposed to similar concentrations of these air pollutants.

4. Classroom Measurement and Observation

While in the classrooms, two observers selectively tape-recorded two types of information: (1) the acoustic environment, and (2) certain indications of classroom behavior when the teachers were lecturing or otherwise interacting with the entire group of children. Figure 1 is a schematic diagram of the equipment used for recording and analysis.

a. Acoustical

The acoustical measurements are to be regarded as being Type 2 (ANSI S1.4-1971) for two reasons: (1) we were unable to commit, without interruption, two sound level meters as first-stage inputs (see Figure 1), which resulted in differences in the acoustical characteristics of our recordings; and (2) some initial recordings were obtained inadvertently at a tape speed (1.5 ips) that

*Lead and carbon monoxide are used illustratively here. The discussion is pertinent also to other pollutants.

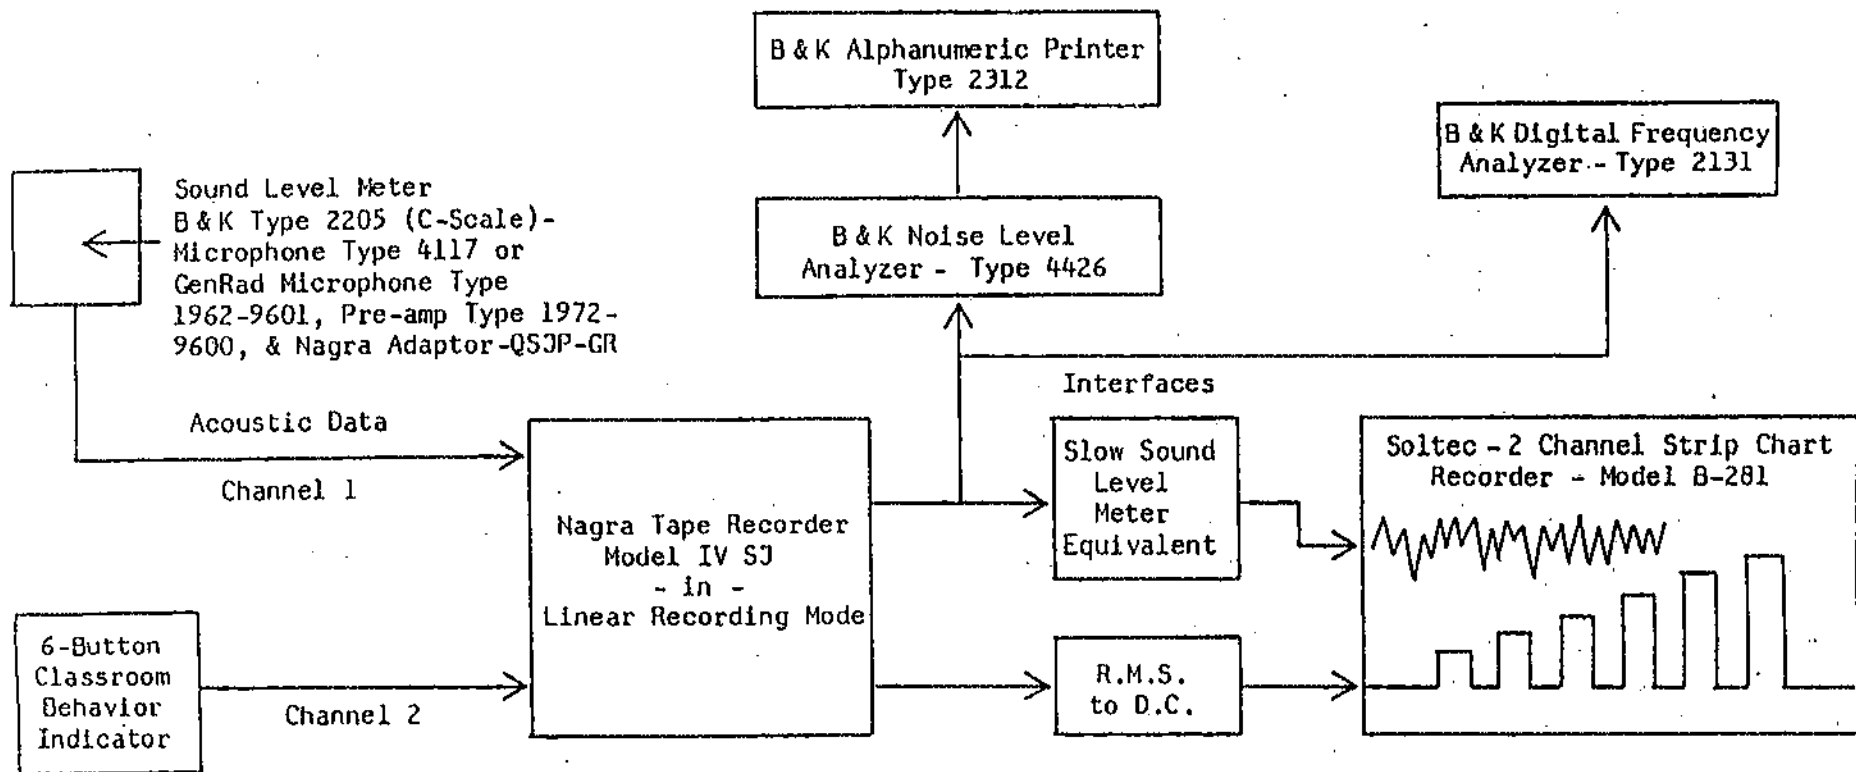

Figure 1

SCHEMATIC DIAGRAM OF RECORDING AND PLAYBACK EQUIPMENT

resulted in the signal to "roll-off" beyond 3,000 Hz.* The acoustical recording system was calibrated daily, and generally before beginning observation.

Noise levels were recorded under three conditions. These were:

- (1) Classroom and school areas without any children. These were obtained during the summer vacation. Ventilation (windows, doors, air conditioners, and forced air) was similar to that observed during the normal classroom periods.
- (2) Classroom noise levels with the children in position but quiet; that is, working at their seats with a minimum of talking and movement.
- (3) The observer's estimate of normal noise levels with the children present and active.

In order to calculate the Articulation Index,⁹ a sample of the teacher's voice level while reading a standard phrase (see Appendix E) at a distance of about 6 feet from the microphone was obtained. We attempted to obtain samples before and after the normal classroom hours without children present, but were hampered by faculty meetings, tardiness, and parent-teacher discussions. We were able, typically, to obtain at least one sample daily from each teacher.

b. Behavioral

In addition to the handwritten observations about the various phases of the school day and behavior therein (see Appendix B), a technique was used to record electronically pulses of varying amplitude on the magnetic tape. These pulses had a carrier frequency of 1,000 Hz, but varied in amplitude depending upon which of six buttons was pushed. Each button corresponded to a specific facet of classroom behavior, and was used to facilitate analysis of the acoustical channel of the tape. The criteria governing use of each button may be found in Appendix F. It is sufficient here to describe the six buttons only briefly:

- (1) Disregard: Used when the noise source that affected some classroom behavior was other than a motor vehicle. This button was used infrequently; discrimination of noise source was based on listening to tape recording or by annotation of the written record.
- (2) Can't Hear: Used when the observer was unable to hear what the teacher or a student was saying.
- (3) Rebuke: Used when the teacher called the class or a student to order.
- (4) Interrupt/Pause: Used when the teacher paused while instructing the students.
- (5) Distract: Used if several students looked around in the direction of a noise source.
- (6) Raise: Used if the teacher's voice was raised to compensate for an increase in noise level. (This event invariably occurred in conjunction with a "Rebuke" rather than as a response to an increase in noise level.)

Table IV shows the frequencies of the various events observed and annotated in the classrooms. It can be noted that Rebukes were the most common event, followed by Can't Hears. Because Rebukes typically were associated with an increase of the teachers' voice levels (Raise), it may be concluded that about 9 percent of Rebukes were concomitant with perceptible increases in the teachers' voice levels.

*Subsequent recordings were at a speed off 3.75 ips, which resulted in the roll-off beginning at 10 KHz.

Table IV

c. Comparability of Observers

After several days of practice in different classrooms, the observers worked simultaneously in a single classroom for two days* in order to determine their relative comparability. Table V shows the frequency of use of the different buttons by the two observers. McNemar's Chi-square test for correlated samples¹⁰ revealed no statistically significant differences in response frequencies between observers. However, observer H appears to have had more difficulty hearing both the students and the teacher than did observer O; and this difficulty is more apparent with respect to hearing the teacher than the students. A reason for H's apparent difficulty is that he has a significant bilateral high frequency hearing loss, as is shown in Table VI.

Detailed analysis of the strip charts (see Figure 1) indicated that the observers were more consistent than the aggregated data (Table V) initially suggested. This analysis compared only those segments of the classroom periods when observations were simultaneous.¹¹ These strip charts were synchronized, divided into 5-second periods, and a count made of the number of coincidental observations as well as the number of 5-second periods during which coincidental observations were possible. The results are shown in Table VI. Section A of the Table refers to the frequency of use of all six behavioral categories, while Sections B and C refer only to "Can't Hear" responses during periods when either the students or the teachers were doing most of the talking. For example, Section B is the sum of two periods when the children were giving answers to arithmetic problems or spelling words, and Section C is the sum of two periods when the teacher was reading a story aloud. Table VI indicates that overall the observers agreed with each other about 93% of the time. Of greater interest, however, is the indication that the observers couldn't hear the students about twice as frequently (12.6% in contrast to 6.7%) as they couldn't hear the teacher. This difference in frequencies of not hearing and hearing the teachers versus the students was statistically significant ($X^2=5.45$, $p < .025$) and is mainly due to the frequencies of not hearing rather than the frequencies of possibly hearing (the Hear-Hear cell).

*Cooperation of Ms. Nancy Ferguson is acknowledged with gratitude.

Table VI
HEARING LEVELS IN dB RE ANSI 1969

Frequency in KHz:	Right Ear								Left Ear							
	.25	.5	1	2	3	4	6	8	.25	.5	1	2	3	4	6	8
Observer																
H	10	15	10	5	20	60	85	80	10	15	0	5	15	70	85	55
O	20	20	5	10	10	15	25	15	15	10	5	5	10	10	15	15

On the basis of the aggregate results shown in Table V it is suggested that observer H had somewhat more difficulty hearing both the teacher and students than did observer O. As shown in Table VII, that initial impression was confirmed;* however, the differences are not pronounced. It may be concluded, therefore, that the observers were responding similarly to each other and their reliability is at least 91% across all response categories.

Table VIII shows the average increases in noise level when the observers were unable to hear what the students or teacher were saying and the background noise levels (see footnote, Table VIII) prior to the Can't Hear responses. It can be seen that for both observers the changes in noise levels were usually greater when the observers were unable to hear the teacher than when they were unable to hear the students, although the background noise levels before the events were very similar. This difference, roughly 2 dB, reflects the fact that the teacher's voice level at the rear of the classroom typically was more intense than was the background noise level; hence, higher noise levels could occur before the observers were unable to hear what the teacher was saying. In contrast, the childrens' voices (sixth graders) probably were less intense,¹² so smaller increases in noise level caused interruption of comprehension of their speech.

The classroom in which these observations occurred overlooked a thoroughfare that handled automobile and truck traffic to and from two freeways. Thus, the background noise levels were high (see the dBC levels in Table VIII). These background noise levels were obtained when children were not present and during a brief period when, apparently, traffic was heavier than usual, as determined by listening to the tapes. Hence, the C-weighted levels without the children present were higher* than with the children, whereas the A-weighted levels were more similar but in the opposite direction; that is, A-weighted levels with children are higher than without children. The increased A-weighted levels were probably due to the voices of students and teacher (compare L_{eq}^A before with L_{eq} without children, for example).

*Observer H heard the students 84.8% of the time (81.8 + 3.0), whereas observer O heard the students 84.3% (81.8 + 2.5) of the time; and for hearing the teacher the percentages are 89.4 and 88.4, respectively.

*Traffic, particularly that containing trucks, has a spectrum showing maximum acoustical energy at frequencies below about 150 Hz. These frequencies contribute much to C-weighted noise levels but are de-emphasized in A-weighted measurements. See K.D. Kryter,¹³ pages 14, 352 and 353.

*

In general we attempted to measure noise levels before an event simultaneously, but were not always successful for the reason explained below, and because of differences between observers as to when to begin or stop analysis of noise levels before an event.

Sample sizes are different for the two observers because they used the button at different frequencies. For example, suppose observer H pushed the Can't Hear button twice during two contiguous 5-second periods, while observer O used it once during the second period; thus, the latter Can't Hear responses were coincidental. In this circumstance the noise levels before the Can't Hear of observer H were measured about 10 seconds before the event, while for observer O they were measured about 5 seconds before the event. In other words, although the button pushes were roughly coincidental, the noise level measurements before any event were not necessarily coincidental.

C. Academic Achievement

In April and May of the school year, third and sixth grade students in the Los Angeles Unified School District are routinely administered two standardized achievement tests. The Comprehensive Test of Basic Skills (CTBS)¹⁴ is administered by the School District, while the California Assessment Program (CAP)¹⁵ is administered by the California Department of Education. Details about these tests can be found in the manuals referenced but the tests are described briefly below.

1. Comprehensive Test of Basic Skills (CTBS)

The test battery is comprised of tests in six basic skills areas: Reading, Language, Mathematics, Reference Skills, Science, and Social Studies. The tests are designed to assess individual achievement. Only Reading and Mathematics were tested typically in our group of schools.

Reading Vocabulary and Comprehension are subtests of the Reading test and contain 40 and 45 items, respectively. Each item of the Vocabulary subtest consists of a stem phrase and four discrete words for alternatives. The student is required to choose a synonym for the key word in the stem phrase. Although the key word is part of a phrase, sentence or paragraph, the vocabulary test is a measure of the student's knowledge of the dictionary definition of the word as the context must be used to determine the key word's meaning. The items of reading comprehension assess specific skills in literal and critical comprehension; about half of the items are of each type. Forty-five items of this subtest are based upon seven selected reading passages. Some passages portray situations, feelings and emotions experienced by young people, while others provide informative material.

The Mathematics section includes sections on Computation (48 items), Concepts (25 items), and Applications (25 items). Items in addition, subtraction, multiplication and division comprise the computation section. The content of the Concepts section includes items on number systems, measurement, set theory, and geometry, and test the student's ability to convert numerical, graphic, or verbal concepts to another form. Mathematical application measures ability to select and complete problem-solving operation and include items on reasoning, algebra, measurement and set theory.

2. California Assessment Program (CAP)

The purposes of the Program are to determine the effectiveness of education in California and to provide information needed to assess the strengths and weaknesses of various educational programs in individual schools and their districts. In contrast to the CTBS, the CAP is not designed to test achievement of individual students. The CAP uses a "Matrix Sampling" technique in which each child is tested on only a small number of the questions comprising the entire test. Test scores are then aggregated over a classroom or over a grade level within a school.

The total test is comprised of 250 items; however, the test form used by any pupil contains only 25 items. Third graders took only the Reading test. Subtests of reading include Word Identification Skills, Vocabulary, Comprehension and Study-Locational Skills. The Vocabulary and Comprehension items are similar in content to those described for the CTBS. Word Identification includes items designed to measure a student's ability to identify specific words, to decode letters to their corresponding sounds, and to identify specific elements within words (e.g., root words and suffixes). Study-locational skills are those that deal with the student's ability to alphabetize and use a table of contents.

Sixth grade children were tested in Reading and Mathematics. The subtests of the sixth grade reading test are identical to those of the third grade test. The mathematics subtests are arithmetic, geometry, measurement, and probability and statistics. Each subtest includes items to assess skills in computation or knowledge, comprehension, and application of mathematical concepts.

D. Data Analysis

Because of the variability in socioeconomic composition and in noise levels in the classrooms and communities of both noisy and quiet schools, a multiple regression analysis was conducted.¹⁶

While planning the study, we hoped to conduct our analysis between classrooms; that is, in a given school a comparison of noisy and quiet classrooms was planned. However, this plan became infeasible after we observed the daily operations of the schools.

Our observations and discussions with teachers and principals indicated that achievement scores of the various classrooms at each grade level within a school should be averaged for the following reasons:

- (1) Many children moved from their homerooms to another room for reading, mathematics, or another subject depending upon skills and interests of the students and teachers, or if a teacher was absent and a substitute was not available. Thus, in many cases noise exposures may have varied with subject matter.
- (2) In some schools students of varying academic skills were not randomly distributed between classrooms. As an example, see the discussion in Section A.2. (Classrooms Combined) regarding the classroom assignments of non-English-speaking children. Thus, some variability in achievement was associated with classroom assignment.
- (3) Achievement scores between classrooms within a school were not consistently statistically different (see below).
- (4) Socioeconomic and community noise variables were available only on a community-wide basis; that is, they were not specific to a classroom or to a student within a classroom, whereas the CTBS scores were specific to each child. Noise levels within the schools were appropriate for each classroom. It appeared preferable, therefore, to use data based upon relatively uniform units of observation: at grade level within a school.

Results

A. Academic Achievement

At the outset, it should be noted that the achievement data of the English-speaking (E.S.) and non-English-speaking (N.E.S.) children are treated separately. This was necessary because, as expected, N.E.S. children do less well academically than do children who are fluent in English, particularly in reading. Differences between English and non-English-speaking children are less apparent for mathematics. Table IX shows the range of Grade Equivalents in Reading and Mathematics for all of the classrooms and schools studied. Grade Equivalents are used because they are more meaningful to the reader than are Expanded Standard Scores.¹⁷

Also shown in Table IX are the F ratios between mean achievement scores for the classrooms in each school and the corresponding degrees of freedom (df). In the df column the number to the left of the comma is pertinent to the number of classrooms, while the number to the right refers to the number of students in the different classrooms. In some schools the number of N.E.S. students was so small as to preclude calculation of meaningful F ratios; nevertheless, the mean achievement for those students is shown. In other schools (e.g., school, 6802, Grade 3), the number of N.E.S. students in each classroom

* Percentiles relative to all other 3rd or 6th grades in schools throughout the State of California. They are based upon the mean percent correct.

** () For comparison these are the percentiles for the CTBS Test (Table XII) relative to samples of students completing 3rd and 6th grades throughout the United States.

*** The socioeconomic mix in School 9004 was similar to that of 9251. Thus, they may be compared.

was admittedly small, but the analysis of variance was completed simply to show the trend.

Comparison of the grade equivalents for E.S. and N.E.S. will show that the N.E.S. students were almost uniformly behind their English-speaking schoolmates. The exception was among the 6th graders in school 7941, where their reading achievement scores were equivalent. But note that among the N.E.S. students within each school, achievement in Mathematics, which is somewhat less language dependent, is greater than that in reading. A similar trend is found among the English-fluent students, but is less consistent and less pronounced than in the case of N.E.S. children.

Table IX shows also the schools in which statistically significant differences in achievement scores between classrooms were attained. As shown in Table X, the distribution of these significant differences suggests that the E.S. students are more likely to show differences in achievement between classrooms than are the N.E.S. students. Although the distributions for the sixth grade students are not significant statistically, they exhibit the trend shown by third grades. However, these distributions may simply reflect the lack of power of the Analysis of Variance test when samples are small. Hence, it is reasonable to be cautious when interpreting the achievement data for the English-weak students.

1. An Overview of Measures of Achievement

Table XI shows the average achievement in Reading and Mathematics in the noisy and quiet schools that are similar with respect to the socioeconomic variables. Four noisy schools which had Hispanic populations of 92 percent or more are not included because comparable quiet schools were not available. Data from these four schools are included subsequently in the multiple regression equations.

With respect to Table XII, it is apparent that both third and sixth grade children in noisy schools generally did less well academically in both Reading and Mathematics than did their counterparts in quieter schools. On average, third graders in noisy schools were about 0.4 year behind in Reading, while the sixth graders were about 0.7 year behind. In Mathematics, third graders in noisy schools were about 0.2 year behind, while the sixth graders in noisy schools were about 0.2 year ahead. This reversal was due to the superior performance in Mathematics by both sixth grade classrooms in a single school, no. 6802. Why these children did so well is unknown; because of the small number of classrooms in this school and in this subset of the Mathematics data, the results should not be interpreted too broadly.

On the average, this group of schools is not "up to par". After approximately three years in school the third graders should have grade equivalents of nearly 4.0, while the sixth graders should be at or near 7.0.

It is of interest to note that the children in most of the schools had slightly better scores in Mathematics than in Reading. This result may be partially due to the test and normative group used as is suggested by the scores obtained on the CAP test shown in Table XIII. These data are in the form of percent correct, and in this form are difficult to interpret because of a lack of normative data. Therefore, shown at the bottom of Table XIII are percentile ranks corresponding to the mean percent correct. It is expected that an average number of correct responses for a particular grade level would correspond to the 50th percentile. With respect to better performance in Mathematics than in Reading, it will be seen that when only California schools are compared sixth grade children in noisy schools were 2 percentile points higher in Mathematics, while in quiet schools equivalent percentiles in Reading and Mathematics were obtained. If comparison is based upon a sample of the students throughout the U.S. (in parenthesis), it will be seen that in the quiet sixth grades performance in Mathematics was poorer than it was in Reading.

6	-.478	-.420	-.337	-.544	-.239	-.327	-.142	-.051

* Limitations of the equipment and time precluded C-weighted measurements. Thus, the neighborhood noise levels are A-weighted.

Aside from certain small discrepancies, the trend of the data for quiet versus noisy schools is consistent for both tests; children in quiet schools attained higher achievement scores than did children in noisy schools. It should be noted, however, that some of our so-called quiet schools were, unexpectedly, not quiet, and their noise exposures may account for the poor achievement shown. For example, school 9004 was located on a thoroughfare that fed traffic, including many trucks, to and from a nearby freeway. This school was also under a segment of the approach pattern to Los Angeles International Airport. The average noise level outdoors at this school was 60 dBA (L_{eq} , measured outdoors for 8 hours). In comparison, at three of the so-called noisy schools the noise levels were about 62 dBA, and at the next quieter school (6893) noise levels outdoors were 58 dBA. Individual classroom noise levels depended upon the orientation of the classroom to the predominant noise source in the area. Thus, the distinction between "noisy" and "quiet" schools was found to be based upon small differences in noise levels; A multiple correlation paradigm was selected for statistical analysis because it takes these small differences into account.

B. Noise Levels in Classrooms

The noise levels, their predominant sources, and the articulation indices observed, or estimated, in the classrooms are shown in Tables XIV and XV. It is apparent that there was a broad range of noise levels in the various classrooms of both noisy and quiet schools. On the average the designated noisy schools were noisier than were the quiet schools, but in comparing individual classrooms some notable exceptions may be found. For example, in the third grade classroom 47 of school 7651 (Table XIV) the C-weighted L_1 level due to an air-conditioner was 63 dB, while in 5 classrooms exposed to local traffic in school 9004, L_1 's were 64 dB. In classroom 17 of school 9004 which was exposed to truck traffic on an adjacent street, the A-weighted L_1 was 5 dB higher than was a comparable classroom in 7651 which was near a freeway. The effect of local truck traffic on classroom noise levels in these two schools is even more pronounced in the case of certain sixth grade classrooms (Table XV). In school 9004, the 4 sixth grade classrooms are arranged in an L shape, in which classrooms 4 and 5 are the base of the L and parallel to the street; the narrow, windowless side of classroom 4 is facing oncoming traffic on the near-side of the street. Classrooms 6 and 7 make up the side of the L and are partially shielded from outgoing traffic by an adjacent building. The center of the window side of classroom 7 is about 100 feet from the centerline of the nearest traffic lane. The observed noise levels in the four classrooms were consistent with the configuration of the rooms but, more importantly, in two classrooms noise levels were found to be much higher than those observed in its matching noisy school.

Other, similar comparisons of schools and classrooms can be drawn. The point is that the so-called quiet schools were in many instances noisier than were the so-called noisy schools. Our analysis required that the noise levels in classrooms be accounted for regardless of whether the source of the noise was a freeway, local traffic, or air-conditioning.

C. Correlations Between Noise Levels and Achievement

Table XVI shows the correlation coefficients between noise levels as measured by the several descriptors in question averaged over the classrooms in each school and the achievement scores averaged over the same classrooms using the CTBS test results. The CTBS, rather than the CAP, is emphasized because performance on the CTBS can be evaluated with respect to some expected criterion. For example, children completing the third grade should attain a grade equivalent of about 4.0. Thus, grade equivalents provide a norm against which the effects of noise can be evaluated.

The magnitudes* of the coefficients shown in Table XVI suggest that noise had a more systematic effect upon sixth graders than upon third graders and that noise appears to have more predictable effects upon the skills involved in Reading than those in Mathematics.

A likely reason for the difference between Reading and Mathematics is that acquiring skills in reading depends more upon verbal interactions between teacher and student and the need for the teacher to correct student errors, for example in pronunciation. Such interactions are known to be affected by noise. Performance in Mathematics, in contrast, is more dependent upon solitary student practice and the student learning to perceive and understand abstract relationships; such tasks are less likely to be affected by noise. This hypothesis is supported by the relationships between scores on the Reading and Mathematics tests and the Articulation Index (AI), which is a measure of how well one is likely to understand speech spoken at a certain intensity given some intensity and spectrum of noise in the background. In general, the correlations between Reading scores and the AI are small but positive (see Appendix G for details), whereas they are smaller (nearly zero) but negative with respect to Mathematics. In other words, as the AI improves Reading performance also tends to improve, but for Mathematics there is only a slight or negative relationship.

The reasons for the generally smaller coefficients for third graders than for sixth graders are unclear. In part, they may be due to a statistical artifact. The range of achievement scores for third graders was much smaller (for Reading, from 2.2 to 4.1) as compared to a range from 4.3 to 8.4 for sixth graders. It is also possible that the data reflect to some degree the cumulative interaction of noise and achievement.* Deficits in achievement due to noise in the first several years of school may become progressively greater as a child continues through school, so that in grade six noise may be more disruptive because it is acting upon a weaker scholastic base.

Similarly, Bronzaft reported (during the Acoustical Society of America's meeting in Los Angeles Ca, on 20 November 1980) that the effects of elevated train noise were less pronounced on the reading scores of third graders than on those of sixth graders. She attributed the difference to sixth graders obtaining less individual attention from the teachers than did third graders. We observed little difference in the amount of individual instruction given third and sixth graders.

1. Preferred Classroom Noise Descriptor and Predicted Achievement

One question posed in the Introduction is which of several descriptors of noise is the best predictor of the relationship between noise and academic achievement. The subsequent statistical question is which noise descriptor is correlated most highly with academic achievement. Implicitly, State law says L_1 * is, whereas the FHWA's Guidelines say an L_{10} is correlated more highly with achievement.

Furthermore, the State suggests that a significant detrimental effect on the educational process begins when a noise level of 50 dBA is obtained, while the Federal Guidelines suggest such an effect begins at 63 dBA.

If we confine attention to Reading achievement in Table XVI, it is quite clear that for both third and sixth graders the C-weighted descriptors of noise level are more highly correlated with Reading achievement than are the A-weighted levels. Furthermore, the coefficients associated with the L_1 descriptors are higher than with the

*We are considering here only the absolute magnitude of the coefficients, regardless of whether they are statistically significant.

*In this regard it is important to observe that on the average approximately 65 percent of the students attended these schools since Kindergarten.

*California State Law specifies the noise level in terms of a single event maximum or peak level. In usage, however, the law is less restrictive. For our purposes, the L_1 level appears appropriate.

L_{10} descriptor; the L_{eq} descriptor is nearly equivalent to or higher than that of the L_1 . These results suggest that L_1 or L_{eq} C-weighted should be used in the multiple regression equation to predict achievement. Several noise descriptors could be used in the calculations, but because of the high intercorrelations between the descriptors (Appendix G), and the need to obtain a single descriptor and level to be used as a criterion level for purposes of noise abatement, only a single descriptor is used in the equation. It is the L_{eq} C-weighted.

2. Preferred Community Noise Descriptor and Predicted Achievement

As shown in Table XVII, noise levels in the neighborhoods appear to be related to childrens' achievement. Noise levels in the communities appear to have a greater effect upon achievement in reading than in mathematics, but the trend is somewhat less consistent than was the case for classroom noise levels. For example, with respect to the reading achievement of third graders, the L_{10} coefficient is greater than is that of the L_1 or L_{eq} . However, in both grades the L_{99} levels are most highly correlated with reading achievement, while for mathematics the L_{99} levels are less highly correlated than are some of the other descriptors. These variations may be statistical artifacts due to the small number of schools.

For purposes of the multiple regression equation, the L_1 descriptor was used because it had the smallest range of coefficients (from $-.327$ to $-.420$), and is perhaps the better estimate of the actual correlation between community noise levels and achievement in both reading and mathematics. Furthermore, the noise events associated with L_1 are more likely than are L_{99} events to intrude into the home.

3. Socioeconomic Variables

Table XVIII shows the correlations between certain socioeconomic variables, achievement, and selected noise measures. These data indicate that as the percentage of families in poverty increases, achievement in reading and mathematics decreases. A similar relationship exists with respect to the percentage of Blacks in the community. In contrast, as the Hispanic population increases there appears to be a trend for higher achievement in mathematics, but no such trend is apparent with respect to reading achievement. This may be due to the fact that, on the average, as the Hispanic population increases there is a corresponding decrease in the percentage of that population which is fluent in English.

As the White population increases, there is higher achievement in both reading and mathematics. The percentages of Blacks and Whites were included in the multiple regression equation because achievement appears to be related to these ratios and because the intercorrelation of these percentages is relatively small (≈ -0.4) as compared to the intercorrelation of the percentages of Blacks and Hispanics (≈ -0.9) (see Appendix G).

Several trends in the data shown on the right side of Table XVIII are of interest. It is apparent that as noise levels in the community increase, median family incomes decrease; or poor people live in noisier neighborhoods. Whites live in quieter communities and attend quieter schools than do Hispanics. Blacks appear to go to quieter schools than do Hispanics, but the Blacks live in somewhat noisier neighborhoods.

D. Predicting Achievement from the Selected Noise and Socioeconomic Variables

Figure 2 illustrates the predicted¹⁸ relationship between Reading grade equivalent in third graders as a function of noise level (in units of L_{eq} C-weighted) averaged over the classrooms in each school, with different average noise levels (in units of L_1 A-weighted) in the 15 communities. Different proportions of Black and White students may be assumed;

Table XVIII

COEFFICIENTS OF CORRELATION BETWEEN SOCIOECONOMIC VARIABLES, ACHIEVEMENT IN READING AND MATHEMATICS, AND INTERCORRELATIONS BETWEEN SELECTED VARIABLES

	Grade Level	Median Family Income	% Families In Poverty	% Black	% Hispanic	% White	Variable	Median Family Income	% Black	% Hispanic	% White
READING	3	.217	-.325	-.342	.021	.697	Classroom* Leq C	.103	-.243	.385	-.257

							% Poverty	-.343	-.028	.267	-.524
READING	6	.360	-.545	-.439	.104	.676	Classroom* Leq C	.035	-.201	.291	-.218
MATHEMATICS	6	.328	-.437	-.667	.408	.493	Community L ₁ A	-.573	.178	-.033	-.408
							% Poverty	-.416	.038	.153	-.493

*These coefficients were calculated from noise levels measured in each classroom, but the other variables were community-wide aggregates.

Figure 2

RELATIONSHIP BETWEEN READING ACHIEVEMENT OF THIRD GRADERS AND CLASSROOM NOISE LEVELS GIVEN DIFFERENT NOISE LEVELS IN COMMUNITIES
The Population is Assumed to be 23 Percent Black and 24 Percent White

The upper curves illustrate the estimated relationship between reading achievement and noise levels in the classroom and the community assuming that the racial composition of the schools is 23% Black and 24% White, 46% Hispanic and 7% other. It shows that at any given classroom noise level as the noise level in the community increases, reading achievement decreases. Conversely, at a constant noise level in the community, achievement in reading decreases directly with increasing noise level in the classroom. The lowest curve shows the results for this sample of schools in which the racial and noise level parameters differ from those assumed for the upper curves. Because the curves are parallel, decreased noise levels in the communities should result in a shift upward of the lowermost curve.

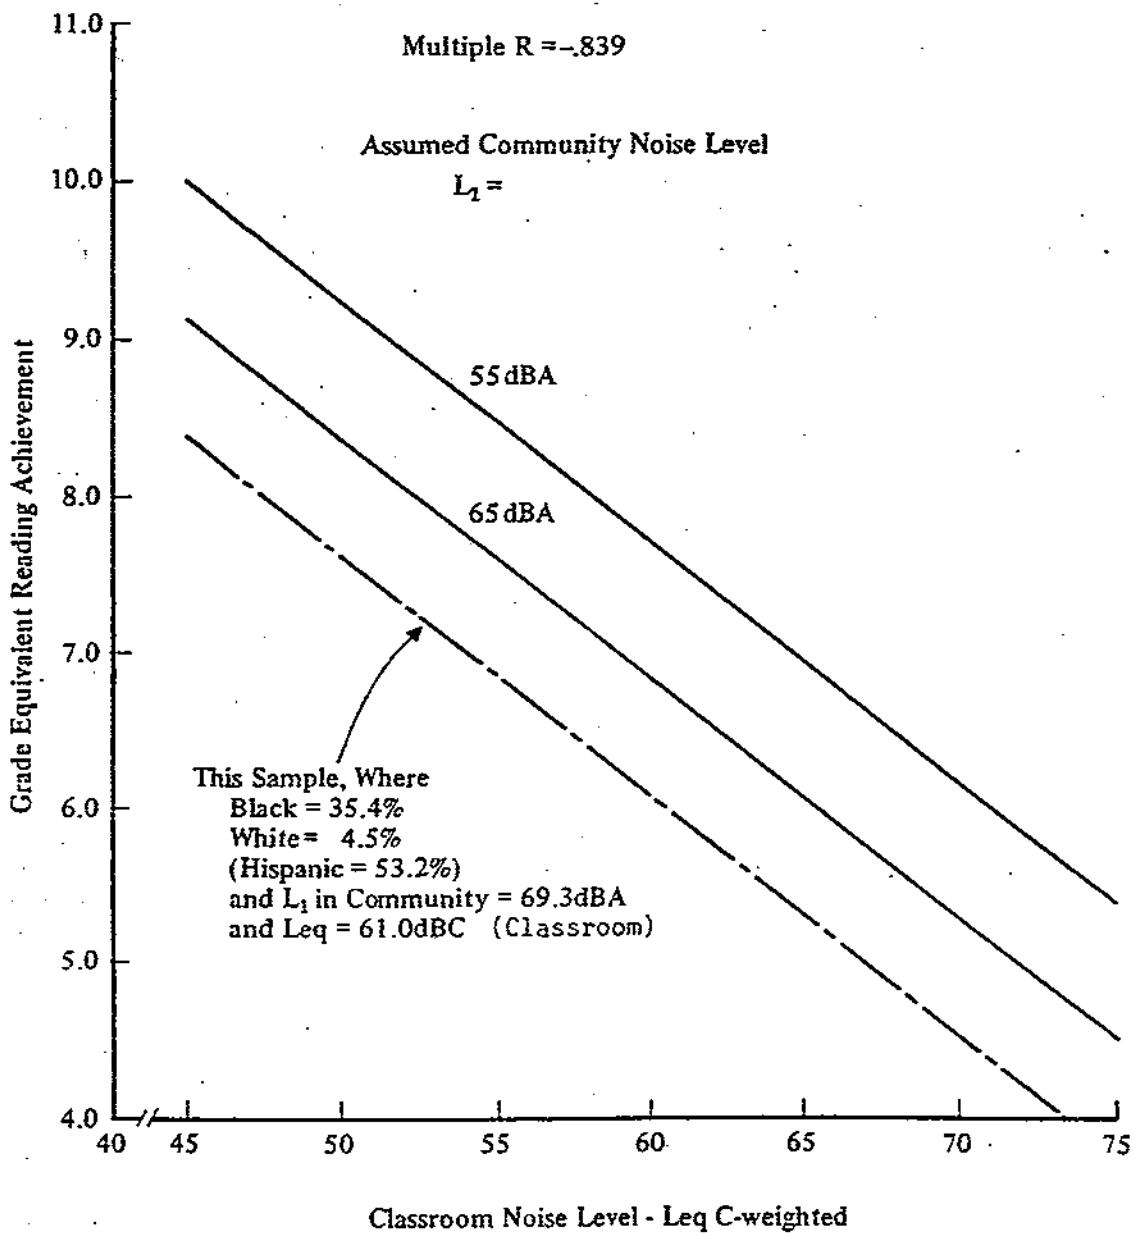

Figure 3

RELATIONSHIP BETWEEN READING ACHIEVEMENT OF SIXTH GRADERS AND CLASSROOM NOISE LEVELS GIVEN DIFFERENT NOISE LEVELS IN COMMUNITIES
The Population is Assumed to be 23 Percent Black and 24 Percent White

School District: 23 percent Black and 24 percent White.

Most remarkable about these data is the apparent trade-off between noise levels in the community and those in the classroom. In other words, if the community is quiet, more noise in the classroom can be tolerated without appreciable effect upon reading. For these third graders it appears that a 10 dB increase in community noise level is equivalent to about a 20 dB increase in classroom noise level. The magnitude of this trade-off is due to the low correlations between reading achievement and noise levels in the classrooms and communities, which in turn may be due to the limited range (1.9 G.E. units) of achievement. Indeed, the multiple correlation does not attain statistical significance.

In Figure 2, the bottom, dashed line represents the results for this sample of schools given its average racial composition and the average community noise level. Clearly, on average this group of students was not achieving at grade level; that is, near or at 4.0. Rather, average achievement was 2.9 units in reading. The highest achievement was attained at a single school with a grade equivalent of 4.1, the lowest was 2.2.

Because the multiple correlation was not statistically significant, and because of suggested possible cumulative effects of an early educational deficit, it appears unwise to belabor further the third graders' data.

As is illustrated in Figure 3, the effects of noise level in classrooms were more pronounced with sixth graders than was the case with third graders. Here a 10 dB increase in classroom noise level resulted in a decrease of about 1.5 grade equivalent units, or about .15 units per dB. Community noise levels have less effect; a 0.9 grade unit decrease for a 10 dB increase in noise level, or about 0.1 grade unit per dB. It is worthwhile to note that the degradation in reading with increases in community noise level is consistent with the findings of Cohen, Glass and Singer.⁵

E. Results with Non-English-Fluent Children

The Correlations between achievement in reading and mathematics and classroom noise levels for the non-English-speaking and English-weak students are invariably low; details may be found in Tables G-3 and G-4. It is likely that this is a result of the students' general inability to read and understand the English language, as is reflected in their generally low and narrow range of achievement scores (see Table IX). It is reasonable, therefore, not to discuss these data further.

F. Implications Regarding Classroom Noise Levels

Because of the trade-off between classroom and community noise levels, it is clear that the proscribed level for classrooms depends upon the noise level obtained or that which may be proscribed for the communities. Our sample of communities had average L_1 levels of 69.3 dBA or an $L_{eq} = 60$ dBA. The effects of those levels on the childrens' achievement are shown in the lowermost curve of Figure 3. Again, as in Figure 2, the socioeconomic variables are those found in our sample. Use of the lowermost curve to establish a criterion classroom noise level appears unwarranted because the percentage of White children is low while the percentage of Black (and Hispanic, as well) children is high as compared to their distribution throughout the school district. Consequently, at this time it seems advisable to use one of the upper three curves to establish the criterion level. We have selected an $L_1 = 65$ dBA as a criterion community noise level for several reasons: 1. It is equivalent approximately to an $L_{dn} = 60$ dBA, which is the estimated exposure of about 54 percent of the urban population of the U.S.;¹⁹ 2. An L_{dn} of 60 dBA is near the upper limit for single family residential areas recommended in California;²⁰ 3. It encompasses the FHWA criterion for highway noise impacting upon a sensitive outdoor space of $L_{dn} = 60$ dBA;²¹ and 4. The reduction of noise levels in urban communities to more satisfactory levels is likely to be a slow process.

Assuming that the average achievement of children completing the sixth grade should be about 7.0 grade equivalent units, Figure 3 indicates that the L_{eq} C-weighted in the classroom should not exceed 59 dB. This level in units of L_{eq} A-weighted is about 46 dB, and equivalent to an $L_{10} = 48$ dBA. It is interesting to note that this latter level is only about 2 dB higher than that recommended ($L_{10} = 46$ dBA) in the National Cooperative Highway Research Program Report No. 117, which was based primarily upon degradation of the Articulation Index by noise. This document apparently was used to establish the federal noise abatement criterion level.

G. Classroom Behavior

Tables XIX and XX present average noise levels in units of L_{eq} C-weighted under three classroom conditions: without children, with quiet children, and with typical activities ongoing. Children were considered to be quiet when they were working individually in their workbooks, for example, and there was no verbal interaction between students and teacher, although some students may have been talking together. Typical activities were those in which the children and teachers were interacting, some children may have been moving around, and some were perhaps shuffling papers, pencils, feet, etc. The tables also include the changes in noise levels relative to the typical level that precluded hearing what the teachers and students were saying, the Articulation Index given the teachers' voice levels, and an estimate of the relative incidence per unit of time that the observers were unable to hear the teachers and students. This latter number is a rough estimate because of the problem of determining, on the basis of the daily classroom log, the exact number of minutes or number of opportunities during some activity when the teacher and students were attempting to communicate verbally. For example, during a session devoted to spelling, the teacher may call out a word to be spelled, she or he then looks around the room for hands or otherwise selects a student to respond, calls a name, repeats the word, at which time and after some delay the student attempts to spell it. Although the time used by the teacher to speak the word, the student's name, and the student's response may be brief, the intervals between these events are of variable and of unspecified duration. Furthermore, preparation times for activities such as putting word lists away before a spelling test or finding a reading book were of highly variable durations and appeared to depend upon the demeanor of the students. Despite the limited value of these results, they are presented herein to provide an approximation of the inability to hear speech in the classrooms studied. When this normalized Can't Hear rate was used as the dependent variable and the other variables (excluding can't hear teacher because of the limited sample) were used as independent variables in a multiple regression equation, the multiple correlation coefficients were low (≈ 0.20 for both third and sixth grade classrooms) and statistically insignificant. The intercorrelation matrix for both grade levels are provided in Appendix H.

The data presented in the two tables discussed above are combined in Table XXI in order to show the average values of the variables aggregated on the basis of whether or not the classroom noise levels without children present exceeded 58 dBC (see Section F. above). Also included are the average voice levels (in L_{eq} -C) of the teachers. In Table XXI it may be seen that in the classrooms with high background noise levels (greater than 58 dBC) the contribution of the children to the noise level is small compared to classrooms in which background levels are at or less than 58 dBC. Specifically, in the noisy classrooms background noise levels prevailed so that when the children were present but quiet noise increased only 1.5 dB (an average over the third and sixth grades), but if typical activities were ongoing noise levels increased by about 3.5 dB. In contrast, in the quieter classrooms the presence of children (due to paper shuffling, some whispering, etc.) added about 8.5 dB to the levels, and typical activity added about 12.5 dB to the background levels. But the fact that similar typical levels were found in both groups of schools suggests that children generate limited amounts of noise. Thus, in schools in noisy areas outside sources of noise prevail, whereas in quiet schools noise generated by the children is

1. Change relative to Typical L_{eq} (During Can't Hear in L_{eq} -C - Typical in L_{eq} -C).
2. Normalized Can't Hear rate for teachers plus students = Total no. of Can't Hear/Number of minutes of observation (estimated from daily classroom log - Appendix B) X 100.
3. Observers were more often unable to hear the students. A single number refers to the number of times an observer was unable to hear the student. The second number refers to an inability to hear the teacher. If the classroom was observed more or less than 3 days, the average incidence per day was calculated and extrapolated to 3 days.*

N.D. No Data. Although there were occasions when the observer was unable to hear students and teachers, they may have occurred when the tape recorder was off.

N.S. No Sample.

E. Articulation Index estimated from noise levels in a comparable classroom.

Inc. Incomplete records.

predominant. Because our typical noise levels include the voices of teachers and children and because at times the child speaking was very close to the microphone, the noise levels when the children were quiet is the better basis for estimating how noise affects classroom communication. Classroom observations indicated that when noise levels due to the children's activities became too high (i.e., at or near the typical levels) the teacher called the class to order and paused until the disrupting activities stopped.

Table XXI indicates that in this group of noisy schools the teachers' voice levels were on the average about 1 dB over the Quiet Children condition; hence, the change in level necessary to obscure the teachers' voices was less than was the case in quiet schools where the teachers' voices were about 3 dB above the Quiet Children condition. It must be remembered that the teachers' voice levels were measured at a distance of six feet, but in the classroom the recordings were obtained when the teacher was at a greater distance. Thus, teachers' voice levels as recorded during the classroom observations probably were about 4 dB less intense (as estimated from Ref. 12) than those shown in the table. In these noisy schools the teachers' voice levels at the back of the room were very near the background noise levels without children present. In these quiet schools, in contrast, at the rear of the class the teachers' voice levels were about 7 dB above the levels without children present, and near the levels observed when the children were quiet.

Because estimates of children's voice levels are unavailable* a similar analysis of their probable intensities at the teacher's ear cannot be made. However, the intensity changes associated with an inability to hear the children are small and typically negative, indicating that the levels during the Can't Hear event were indistinguishable from or less than the typical level. Furthermore, it is reasonable to hypothesize that in these noisy schools the children's voice levels were frequently at or below the levels observed when the children were absent, and that the teacher may have had difficulty hearing ~~what~~^{what} was being said. We observed instances, particularly in noisy classrooms, in which children mispronounced or misspelled a word without correction by the teacher. Presumably, the teacher did not hear the error, and upon subsequent questioning the teacher admitted that she had not heard.

As is to be expected, the articulation indices in this group of noisy classrooms is lower than in the quiet classrooms. In addition, the earlier finding that children in quiet classrooms do better academically than children in noisy classrooms is seen again.

Teachers have observed that as a result of noise children are less well behaved and require more direct control than do children in quieter classrooms. It was thought that a simple test of this observation might be to count the number of rebukes of the children and the number of times a class is called to order to discern if such numbers are related to the classroom noise levels. Hence, Table XXII presents the number of rebukes as an average over classrooms and the average noise levels extant shortly before those rebukes occurred. Noise levels before the event were recorded because of the possibility that a noise threshold must be reached before the teacher calls the class or individual children to order.

It will be seen that there appears to be no relationship between the number of rebukes and the noise levels occurring just before a rebuke. Furthermore, there are no differences in the number of rebukes observed in these groups of noisy and quiet classrooms. These limited data suggest that calls for order were precipitated by levels of about 69 dBC.

In order to assure ourselves that this result was not due to the way the classrooms were divided, we calculated the intercorrelation matrix of the three variables shown in Table XXII and the relative frequency of rebukes based upon total observation time in each

*Pearsons et al.¹² measured voice levels of children under age 13 in an anechoic chamber. Whether children's voices in school have comparable intensities is unclear. Our observations indicate they are less intense. In fact, some children appeared to be whispering at times.

Table XXII

AVERAGE NUMBER OF REBUKES AND NOISE LEVELS
BEFORE THE REBUKE IN CLASSROOMS
CATEGORIZED BY NOISE LEVELS WITHOUT CHILDREN

	L _{eq} Without Children > 58 dBC			L _{eq} Without Children ≤ 58 dBC		
	No Children	Number of Rebukes	L _{eq} C Before a Rebuke.	No Children	Number of Rebukes	L _{eq} C Before a Rebuke
			<u>Third Grades</u>			
Mean	65.3	114.0	69.1	54.2	88.6	69.2
s	5.0	73.6	4.4	2.3	57.3	2.7
			<u>Sixth Grades</u>			
Mean	63.9	51.2	67.7	55.6	82.2	68.9
s	3.0	34.9	5.1	2.3	47.4	2.7

classroom. Correlation coefficients between the noise levels and both rebuke frequency measures were on the order of 0.05.

Discussion

That a negative relationship exists between classroom noise levels and reading achievement has been demonstrated by this study, Bronzaft and McCarthy,² and Cohen, et al.^{3,5} A similar relationship between community noise levels and reading achievement has been shown herein as well as by Cohen, et al.⁵ and Green, et al.²² In these studies the sources of noise were aircraft, freeways and local thoroughfares, and elevated trains. Retrospectively, it is perhaps not surprising that both community and classroom noise levels are correlated with achievement levels if we consider how noise from such sources is propagated throughout the community. Indeed, as was shown in Appendix G, there was a high correlation ($=0.65$) between classroom noise levels in units of L_{eq} -C and background noise levels (L_{99}). Furthermore, the classroom C-weighted levels were more highly correlated with community levels than were the classroom A-weighted levels, which probably reflects the fact that low frequencies propagate more widely and with less attenuation than do the higher frequencies.

What this study and most of the others fail to demonstrate (although some investigators did not try) is the immediate effect of noise on classroom behavior or operations. The exceptional study was that of Crook and Langdon,¹ which showed that as noise from aircraft flyovers intensified there was an increasing incidence of (1) an inability to hear what teachers were saying, (2) pauses by teachers to permit the noise to cease, and (3) increases in the teachers' voice levels in compensation for the noise. In the noisy classrooms of this study, noise events such as passbys of trucks, motorcycles, or noisy automobiles were difficult to measure from the tape recordings because of the generally high background noise levels due to heavy traffic and the ongoing discussions between students and teachers. Thus, an event, although audible, was acoustically indiscernible. Despite this inability to demonstrate certain behavioral effects of noise, the fact that independent studies with a variety of noise sources show less achievement in noisy schools and communities indicates that noise hampers the educational process in some way. Cohen and Weinstein²³ have suggested several possibilities. Moreover, it appears that early academic deficits due to noise become progressively worse. Because of this progressive deficit and because children are exposed to community noise well before their exposures in classrooms, it appears that abatement of community noise should be emphasized more than abatement of classroom noise. Of course, if community noise is abated classroom noise will be also.

Abatement of classroom noise is a relatively simple problem technically* and has been shown to be of some benefit to the students academically.^{3,24} The question of importance for this study was, "What should the criterion noise level be?"

In terms of behavioral effects the results are equivocal, but in terms of academic achievement the results are more clear, notwithstanding the fact that children do contribute to background noise levels. As was pointed out with respect to Table XXI, when the children in noisy schools were relatively quiet the predominant source of noise was traffic. Here the children when quiet added only 1.5 dB to the background traffic level, which might be accounted for by the variance of traffic noise rather than the presence of the children. On the other hand, in the quiet schools the noise level with children quiet was about 3.0 dB quieter than were the noisy schools without children present. If we assume that when children are quiet they produce an L_{eq} of 63 dB C-weighted,* then logarithmic addition of the noise levels observed in the noisy classrooms from traffic alone (64.5 dB as an average over the third and sixth grades) to another random

*Reducing community noise levels is technically and politically difficult because it appears that a major requirement will be to reduce noise levels at their sources, and organized opposition to such attempts has been amply demonstrated during recent history.

*This level is consistent with that reported by Pearsons, et al.¹² Comparison of A- and C-weighted L_{eq} s when only trucks and local traffic were the noise sources indicates that L_{eq} C-weighted - 13 = L_{eq} A-weighted.

noise of 63 dB (children quiet) will result in a total noise level of about 66.5 dB. As may be seen in Table XXI, this is very close to the noise levels observed in the noisy classrooms with children present but quiet. In other words, noise levels from outside sources appear to have a major influence on classroom noise levels when the children are present and quiet. This analysis suggests that noise levels resulting from the presence of quiet children should not be taken into account in developing a criterion noise level for an abatement program.

Furthermore, teachers have the responsibility for controlling noise levels in their classrooms in order to assure that adequate communication is possible, but they have no control over external sources of noise. These external sources may influence their vocal efforts.¹² But, despite these efforts the Articulation Indices calculated in this group of schools show that in noisy classrooms the average (over third and sixth grades) Articulation Index was .77, whereas it was .95 in the quiet classrooms. Although the first number is some 19% less than is the second, according to the usual interpretation of these numbers speech communication should be adequate if the teacher is talking. Our observations indicated that children do not speak as loudly as do the teachers. If we consider that education depends upon interactions between students and teacher, then given the apparently lower voice levels of the students and, at times, their less than ideal distance from the teacher, it can be hypothesized safely that high background noise levels from external sources are a greater detriment to the ability of the teacher to hear the student than is the converse. Indeed, the observers recorded an inability to hear the students about 9 times as frequently as their inability to hear the teacher when all of the data were combined (Table IV), and about twice as frequently when the observation periods of teacher versus students were controlled (Table V). Finally, the changes in level recorded when the observers were unable to hear the children were near or below typical noise levels (see Table XXI), which suggests that discrimination of a single voice from a noise milieu is a difficult task for the teacher and should be accounted for in establishing a criterion level for noise abatement. It is thought that using the reading achievement results, which appear most sensitive to noise, provides conservative but indirect assurance of accounting for the teachers' difficulty.

Conclusion

A recommended design criterion for traffic noise levels inside classrooms ($L_{eq} = 58$ dB C-weighted)²⁵ is advanced on the basis of two independent studies: The one reported herein and the National Cooperative Highway Research Program Report No. 117.²⁶ This recommendation should be accepted as the basis for revision of current standards pending the availability of additional information.

Because of the apparent synergistic effects of community and classroom noise levels on academic achievement, in order for the above classroom noise limit to be effective in preventing degradation of academic achievement from noise, efforts will be required to contain community noise levels so as not to exceed $L_1 = 65$ dBA.

²⁵This level is equivalent, approximately, to an $L_{10} = 48$ dBA, which is 7 dB less than the current Federal standard ($L_{10} = 55$ dBA), but about 6 dBA higher than the California standard ($L_1 = 50$ dBA = $L_{10} = 42$ dBA). Use of the C-weighting is recommended because C-weighted sound level measurements are more sensitive to the lower sound frequencies found in traffic noise and are generally more highly correlated with achievement in reading.

Appendix A

Technique for Estimating Several Socioeconomic Indicators Applicable to the 1978/79 School Year for Selected Schools

Study of census data showed that neighborhoods providing children to a certain school are encompassed by several different census tracts and incorporate only small parts, or "blocks", of the much larger census tracts and in most cases the socioeconomic data (% poverty, median family income, etc.) for each tract were different. Thus, the problem arose of developing a technique for using existing census data - that are applicable to or described in terms of large areas (tracts) - to the specific, smaller neighborhoods feeding children to the specific schools studied.

Technique:

The Los Angeles City Planning Department indicated that the neighborhoods of interest had not had significant changes in the number of dwelling units during the preceding ten years or so. Thus, using the 1970 U.S. Census as a data base, the procedure described below was followed:

1. From maps showing the areas feeding children to our schools and from Census Tract maps - that show Census Block numbers within each tract, we determined the specific Census Blocks that provided children to each of our schools.
2. From the "Census Block Within Tract" data we obtained the number of housing units in each block that contributed children to each school's population.
3. Then we calculated the fractional contribution of a particular block (or blocks) of a tract to a school's population by using the total number of housing units in a tract as the denominator and the number of housing units obtained in Step 2 as the numerator. This fraction was calculated to 3 decimal places.
4. Fractional contributions (Step 3) were calculated for each census tract contributing children to a particular school.
5. The fractional contributions of each tract contributing children to a particular school were multiplied by the median family income, percent in poverty, and percent unemployed for each corresponding tract, and the products summed to arrive at the socioeconomic indicators shown in Table 1.

Mr. Fred Ige of the Los Angeles City Planning Department concurred with the technique, and Mr. Thomas Smuczynski of the Los Angeles City Planning Department provided 1977 estimates of median family income, percent in poverty, and percent unemployed. These 1977 estimates, by census tracts, were obtained from a study conducted by the Planning Department and were based on a two percent sample of households in the City of Los Angeles.

In nine cases the tracts were not in the City of Los Angeles. The 1977 estimates for these tracts were obtained from Urban Decision Systems, Inc., at the suggestion of the Los Angeles County Planning Department.

Jane Rachel Kaplan, Ph.D. was, in large part, responsible for and conducted the described socioeconomic analyses.

Appendix B

Synopsis of a Study Entitled "Effects of Freeway Noise on School Children"

Purpose:

To develop a criterion level for controlling noise from freeways (or other sources) in classrooms.

Method:

In the Los Angeles Unified School District, 20 schools have been selected for study. Half the schools are adjacent to freeways, while the "quiet" ten are not. Quiet schools are used for comparison.

In each school we are concerned only with the third and sixth grades because these grades, by law, are tested relatively extensively for academic achievement. In addition, State law also requires that the children now in grades three and six had their hearing checked the preceding year. Those children with hearing problems have been identified, and can be checked further if necessary.

Typically, we try to study all the third and sixth grades in each school. If this is not possible, the classes studied are selected so they are likely to be the noisiest (nearest the freeway) or quietest (furthest from a playground or noisy street, for example).

We spend three consecutive days in each classroom; hopefully the teacher involved is permanent and experienced at that grade level. In the classroom, we try to set up an observation point that approximates the location of those students who are furthest from the teacher at her/his usual operating position. Typically, the "usual operating position" is at the head of the class in front of the blackboard, from which point the teacher usually lectures the entire class.

Our observations consist of tape recording whatever happens in the classroom, including noise from freeways, airplanes, local streets, playgrounds, children in the classroom and the teacher. These tapes are subsequently analyzed to determine the noise level when certain classroom "events" occur, then the tapes are wiped clean for re-use in another classroom. The "events" are the times that (1) the observer cannot hear what is being said by the teacher or student, (2) the students are distracted by some noise, (3) the teacher rebukes students for not doing their work, or (4) classroom progress is interrupted or delayed while awaiting the cessation of some noisy event. The observer will be making notes on a form during the class. These notes describe what happened in the period and are used to facilitate analysis of the tape. A copy of the form is attached. You can see the forms associated with your class at any time.

A Final Note:

We are in no way evaluating teachers, teaching styles, or content. Please conduct your class as you usually do, ignoring the observer as much as possible. The observer will answer any questions you or the students may have.

Personnel:

Juanita Oñate

Robert Heald

Jerome Lukas

We are members of the Office of Noise Control of the California Department of Health Services.

PROTOCOL AND LOG SHEET FOR CLASSROOM OBSERVERS

School: Street School Room #: 15 Teacher: Mrs. (Subst 2/1) Date: Apr 22, 1979

Appendix C

Results of Monitoring of Noise and Air Quality in Feeder Areas of Schools at Various Proximities to Freeways

Jack W. Swing
California Office of Noise Control
Berkeley, California

Presented at the 98th Meeting of the
Acoustical Society of America
Salt Lake City, Utah

November 28, 1979

I would first like to present an overview of the project which is currently being conducted by Jerome Lukas and myself, and which is concerned with the effects of freeway noise on hearing levels and academic achievement of children. A preview of this study was presented at INTER-NOISE '78 in San Francisco, California.¹ The objectives of this larger study are outlined in Figure 1. The report which I am presenting today is concerned with the first objective, that of determining correlations between environmental noise levels, childrens' exposure levels, hearing loss and academic achievement. The other two items will be discussed in the final report on the entire project. (It is of interest that the State of California presently specifies a maximum intrusion level inside classrooms of 50 dB A-weighted. It is assumed that this maximum level is created by the noisiest vehicles on the road; i.e., heavy trucks.)

Figure 2 illustrates the various data elements which comprise the work efforts in the entire program. Four of these data elements are pertinent to today's discussion. These are: school site noise exposure, feeder area environmental noise, and air quality at both school sites and their surrounding feeder areas. This paper, then, is concerned with the environmental monitoring efforts in both noise and air quality which support the study on the effects of freeway noise on the academic performance of school children.

Figure 3 presents a map of the matched noisy and quiet school feeder areas which were incorporated in this study. Those areas shown in red are the high noise impacted schools and their feeder areas, while those in green are the socioeconomically matched quiet schools and their feeder areas. In total, there were 15 schools and their surrounding feeder areas involved in this study. Originally, 32 schools had been selected for preliminary analysis; this number was then reduced to a more manageable number. Of the 15 schools illustrated on the map, 8 of these were selected for air quality analysis. These schools are indicated by an asterisk adjacent to their feeder areas.

Figure 4 presents additional detail on two of the socioeconomically matched feeder areas that were utilized in this study, and serves to illustrate the general nature of the feeder areas providing children to our study schools. As may be observed, the two areas are in close proximity to each other, with the primary difference being that one area has considerably heavier freeway exposure than the other. The matching of areas has been carefully controlled for such

socioeconomic factors as ethnic population, mean housing values, mean income, percent employed, and other pertinent socioeconomic variables. An interesting item to observe in these two feeder areas is that in one case, school 8501,* there is clearly no freeway impact, while in the case of School 7412, a large portion of the feeder area has the Harbor Freeway running straight down the middle. However, off to the east is a segment of residential development well away from the freeway, whose individual noise environment is very close to that of the 8501 School feeder area. The analysis has been confined to those children which live in the immediate proximity of the schools they attend.

Figure 5 illustrates the scope of the monitoring efforts involved in this study. In the community noise monitoring aspects of the program, 15 school sites and their surrounding feeder areas were studied. This resulted in a total of 141 community noise monitoring sites which, at four to five days per site, yielded a monitoring effort of approximately 500 site days. Approximately 1,600 man-hours were expended on the community noise monitoring efforts. The air quality monitoring, which involved eight school sites, was conducted on a rotational basis during December 1978 and January and February of 1979. The monitoring involved measurements at each of eight schools on ten separate days. At each school site, outdoor lead and carbon monoxide were monitored for 24-hour periods. Indoor carbon monoxide was also monitored for two days at each of the schools during school hours.

In addition to fixed monitors at each school site, a fully-equipped air pollution monitoring van was rotated through the system and spent one entire 24-hour period at each of the school sites, thereby effectively replicating the air quality data taken on any given day at any given school site. Approximately 3,000 man-hours were expended in collecting the air quality data.

The personnel utilized for the noise monitoring efforts in this program were technicians from the California Division of Highways (CalTrans) who had little or no prior experience in noise monitoring. These technicians were, however, quite familiar with the air quality monitoring procedures and equipment. Each technician received approximately two hours training in community noise monitoring techniques prior to beginning the actual field monitoring work.

Given that the program would utilize personnel generally unfamiliar with community noise work, the equipment to be used had to be extremely simple, easy to use, reliable, and essentially foolproof. The Gen Rad Model 1945 Community Noise Analyzer was selected as generally fulfilling these requirements. Ten of these units were incorporated in the noise monitoring efforts, along with security boxes and Gen Rad weatherproof microphone systems. These consisted of installation of "pause" buttons on the devices, as well as reducing the run times by a factor of 3, such that we were able to conduct 10-minute samples rather than the normal sampling run time of 30 minutes. Throughout the duration of the noise monitoring, the Gen Rad units functioned reliably and maintained an operability rate on the order of 90% (i.e., 9 of the 10 were generally running and usable). Overall, less than 5% of all the data collected was either lost or invalidated. Most of these failures were due to operator error - such things as forgetting to set the unit to the proper run schedule, or the most common failure, allowing the unit to operate with insufficient battery voltage.

In addition to the Gen Rad units, two BBN Model 614 instruments were used for spot checks on the other data. These units were used exclusively by State Office of Noise Control personnel, because of their somewhat more sophisticated functional characteristics and higher value. The two BBN units functioned satisfactorily throughout the duration of the study.

I will next discuss the temporal sampling aspects of the study effort. Figure 6 illustrates the essential elements incorporated in selection of the community noise monitoring sites. The basic concept involved in site selection was taken from work done by Sutherland at Wyle Laboratories^{2,3} with modifications per R.K. Miller's techniques.^{4,5} Essentially, each school feeder area was identified (using Wyle's terminology) as the spatial sampling unit (SSU). Within each spatial sampling unit, a combination of systematic techniques (after Wyle) and

*In order to preserve confidentiality, schools are identified by code number only.

deterministic site selection processes (after Miller) were utilized. Only residential areas were monitored. These areas were selected in each feeder area by observing maps of each feeder area and, in most cases, driving through these areas to further subdivide the land uses. Each feeder area encompassed a physical area on the order of 1/4 to 1 square mile (.6 - 2.6 km²). Once the residential land use areas in each spatial sampling unit were identified, they were then subdivided into sub-areas of similar noise exposure, based on comparable proximities to freeways, major arterials, commercial strips, and industrial areas (deterministic subdivision). Typically 4-6 sites per spatial sampling unit were utilized. One may infer from Sutherland's analysis that this would yield a 95% confidence interval on the order of $\pm 4-5$ dB.

The next step was to secure specific measurement locations in each SSU. This involved locating a contact person in each feeder area. Generally, this contact person was the PTA president, the community representative, or the school principal. In some cases we found it useful, when time allowed, to address the PTA or parents' meeting, etc., in order to apprise them of our study efforts and the merit of our program towards improving the quality of education their children would receive. The contact person was responsible for providing names and addresses of interested parents residing in each of the identified sub-areas. The contact person would additionally make the initial personal contact with each prospective candidate and apprise them of the nature of the study. This approach yielded a more-or-less random site selection within each sub-area, which was, however, favorably biased in that each site utilized actually represented one of the school children's residences. Each candidate site was then visited and evaluated for suitability. The criteria for site suitability included the following: No dogs; safe, accessible microphone location; no construction in the immediate proximity of the site. Also, the particular site should not be dominated by any "unusual" noise sources (i.e., gas stations, car washes, dry cleaners, refrigeration compressors, should not be adjacent to delivery truck alleys behind markets, should not be near fire stations or hospitals, etc.). For those sites finally accepted for study, a contract was signed between the homeowner and CalTrans, in which the homeowner would receive \$5.00/day for the use of his premises. This amounted to an expenditure of approximately \$1,320 over the course of the study effort. We found, however, that these payments seemed to insure the cooperation and continued interest of the homeowner, who was also a parent of one of the children involved in the study. These individuals took sufficient interest in the program and in the security of the monitoring equipment, that losses due to theft were limited entirely to a single microphone.

When suitable candidate sites within a given SSU could not be located, it was necessary to substitute roving sites which were sampled on a rotational basis. In all cases we attempted to place the microphone as near the center lot as possible, with the provision that it also be located 20 feet (6.1m) or more from the nearest roadway and away from "high activity" areas around the home (swimming pools, air conditioning units, garages, patios, driveways, etc.). At the fixed sites, the microphone was typically mounted on a mast, 5 feet (1.5m) above the roof, either attached to a plumbing vent, chimney, TV antenna mast, or other means of support, at a typical elevation of 12-14 feet (3.7 - 4.3m). For the roving sites, the microphone height was typically 4-5 feet (1.2 - 1.5m), with its placement in the center of vacant lots in the study area. The generalized nature of the spatial sampling patterns is illustrated in Figure 7. In many cases, however, the ratio of fixed to roving or portable survey sites was other than as illustrated in this figure, due to the variables associated with selection of candidate sites and the general agreeability of the community to participate in the noise monitoring program.

In developing the temporal sampling strategies, again the work of Sutherland was incorporated.² The categories of sampling strategies considered in the program are illustrated in Figure 8. The temporal sampling schedules used in the noise survey are shown in Figure 9, and fall between Wyle's Class 2 and Class 3 measurements, in that nine sample periods per day were utilized at the fixed sites, which amounted to 19 hours of sampling for each 24-hour period. The roving site schedule typically followed Type Class 2 procedures, with monitoring at each site occurring for five to six 30-minute measurement sequences per 24-hour period. These sampling schedules were selected to allow the monitoring efforts to be conducted by two CalTrans technicians working on 8-hour overlapping schedules. In some instances it was necessary to modify

the roving site sampling schedule in order to achieve improved security for measurement personnel.

A sample data sheet for one of the fixed monitoring sites is illustrated in Figure 10. These data sheets have been keyed to the fixed location monitoring schedule of Figure 9 and are designed for use with the Gen Rad 1945 monitoring units. A sample preliminary data analysis control sheet, which illustrates the nature of temporal variations typically found at the fixed site noise monitoring locations, is shown in Figure 11. Equivalent energy levels were plotted as a function of time period and duration of sample for each of the community monitoring sites for each of the days which a particular site was sampled. Thus, after four to five days of monitoring a given site, a "typical" trend could be identified. Data lying clearly outside these "normal" trends were then further evaluated and spot checks were conducted at those sites having questionable data.

The preceding discussion dealt with a description of the spatial and temporal sampling considerations incorporated in the conduct of the noise monitoring efforts. I would next like to present some of the preliminary findings of both the air quality analysis and the community noise monitoring. First, let us consider the air quality data and the variations in air pollutant levels as a function of sampling date and freeway proximity of the measurement sites.

Figure 12 illustrates 24-hour outdoor airborne lead levels by school for each of the 10 sample dates. Three pairs of socioeconomically matched noisy and quiet schools are shown in this figure. As may be observed, all six schools illustrate almost identical trends in terms of lead concentrations as a function of their sample date. Proximity to freeways seems to have little or no effect on the values of the measured lead concentrations. Similar trends are also observed in the 24-hour average carbon monoxide levels at these same six schools for the same sampling dates, as shown in Figure 13. For these schools, again note that freeway proximity has little relevance on the levels of pollutants measured. In fact, almost identical trends as a function of sample dates are seen to exist between 24-hour lead levels and 24-hour carbon monoxide levels. Thus, based on these limited samples, we may conclude that air quality, certainly in the Los Angeles area, is primarily a basin phenomena and does not appear to be dependent upon proximity to a freeway.

Monitoring of interior carbon monoxide levels was also conducted at each of the eight school sites; however, interior levels appeared to show little or no correlation to exterior levels for the same measurement periods. Hence, no conclusions can be drawn at this time based on this study's data as to the effectiveness of the classroom building in lowering or at least otherwise affecting indoor carbon monoxide levels.

Finally, Figure 14 illustrates the temporal characteristics of the measured outdoor carbon monoxide levels for a particular school site. This figure, which is a combination of the data from all 10 sampling days, is quite typical in appearance to the other school sites, and illustrates an interesting phenomena; that during the hours of the day that school is in session, carbon monoxide levels tend to be at their lowest values.

Let me now present some preliminary results of the community noise monitoring. Figure 15 illustrates the average daytime noise exposure expressed in terms of L_{eq} for 8 hours for each of the school sites analyzed. As may be observed, the school sites are generally lumped into two distinct groupings; those in the immediate proximities to freeways, and those in the matched feeder areas away from freeways. The noise impacted school sites in general range from 5-6 dB louder than their quiet counterparts. However, it should be noted that the values represented in this figure are the logarithmic average of exposures at a particular school site, weighted by the number of rooms exposed to a particular level. For this analysis, a minimum of three measurements per school site were taken. These measurements were of the maximum exposed classrooms, minimum exposed classrooms, and the estimated average exposed classrooms. Thus, we could expect the overall range of exposures between noisy and matched quiet school sites to be considerably greater than are shown in this figure.

The day-night sound levels for the school feeder areas are summarized in Figure 16. For this initial analysis, the data has been stratified into freeway impacted and non-freeway exposed community sites. For a sample size of 22 freeway impacted sites, the mean value of observed day-night sound levels was 68.4 dB, with a standard deviation of 4.2. For the non-freeway sites (sample size of 82) the mean day-night sound level was 62 dB; with a sigma of 4.1. For all sites combined, the mean value was found to be 63.3, with an expected higher standard deviation of 4.9 dB. In subsequent analysis, the non-freeway sites will be further stratified in terms of their proximity to low volume local streets, high volume arterials, commercial strips, proximity to industrial areas, and single or multi-family housing units. It is anticipated that this further stratification of the non-freeway sites will yield standard deviations on the order of 2-1/2 - 3 dB.

Finally, the cumulative percentages of the populations in each of the feeder areas studied and their relative exposure to environmental noise (expressed in terms of day-night sound level) are summarized in Figure 17. For each school feeder area, the population exposure is expressed in terms of 10%, 50% and 90% levels, indicating that cumulative percentage of a feeder area's population exposed to a particular noise level. In addition to the measured data, we have shown the predicted ambient environmental noise levels based on population density, taken from BBN's 100 point study for the U.S. Environmental Protection Agency.⁶ Computation of this predicted exposure level in L_{dn} uses the following formulation:

$$L_{dn} = 10 (\log_{10} \rho) + 22, \text{ dB}$$

Where ρ is the population density in thousands of people per square mile.

For this analysis, population density was computed based upon the adjusted area within each school feeder area which reflected only residential land use. As may be observed, these predicted environmental noise levels, based solely on population density, covered a rather narrow range, that being from approximately 60 dB to 66 dB L_{dn} . (The population densities based on this adjusted area concept range from 7,100 people per square mile up to 21,000 persons per square mile.) It should be noted, however, that the BBN analysis was based on the assumption that the areas represented by it were not exposed to freeways or aircraft overflight activity. Therefore, applying such an analysis to the freeway noise impacted feeder areas may not be fully appropriate.

An interesting observation can be made looking at the range of populations exposed to the various environmental levels for matched pairs of school feeder areas. The mean, or 50% population exposed levels, do not vary significantly in any of the matched pairs of feeder areas. The range, however, for the freeway-exposed and non-freeway-exposed areas do show considerable spread, where in all cases, the freeway-exposed areas indicate a much higher range of environmental noise exposures. Ongoing analysis will include additional detail on the percentage of each feeder area's population exposed to environmental noise levels.

In conclusion, the purpose of this environmental monitoring has been to provide the supporting documentation needed to readily assess not only the school childrens' classroom noise environment, but the noise environment in which these children reside. This noise exposure information has been supplemented by air quality monitoring data in order that any adverse effects thought to be noise related can also be correlated with the air quality of the area in which the school is located and in which the children reside. We have been concerned, since the beginning of this project, that there may indeed be synergistic effects of combined high noise exposure and high levels of air pollutants experienced by those children residing near freeways. It would appear, at least from our initial analysis, that adverse effects found in these studies may be related solely to the noise exposure climate of the children, in that the air quality appears to be more or less constant throughout the portion of the Los Angeles Basin in which the study was conducted, and independent of freeway proximity.

EFFECTS OF FREEWAY NOISE ON SCHOOL CHILDREN

STUDY OBJECTIVES

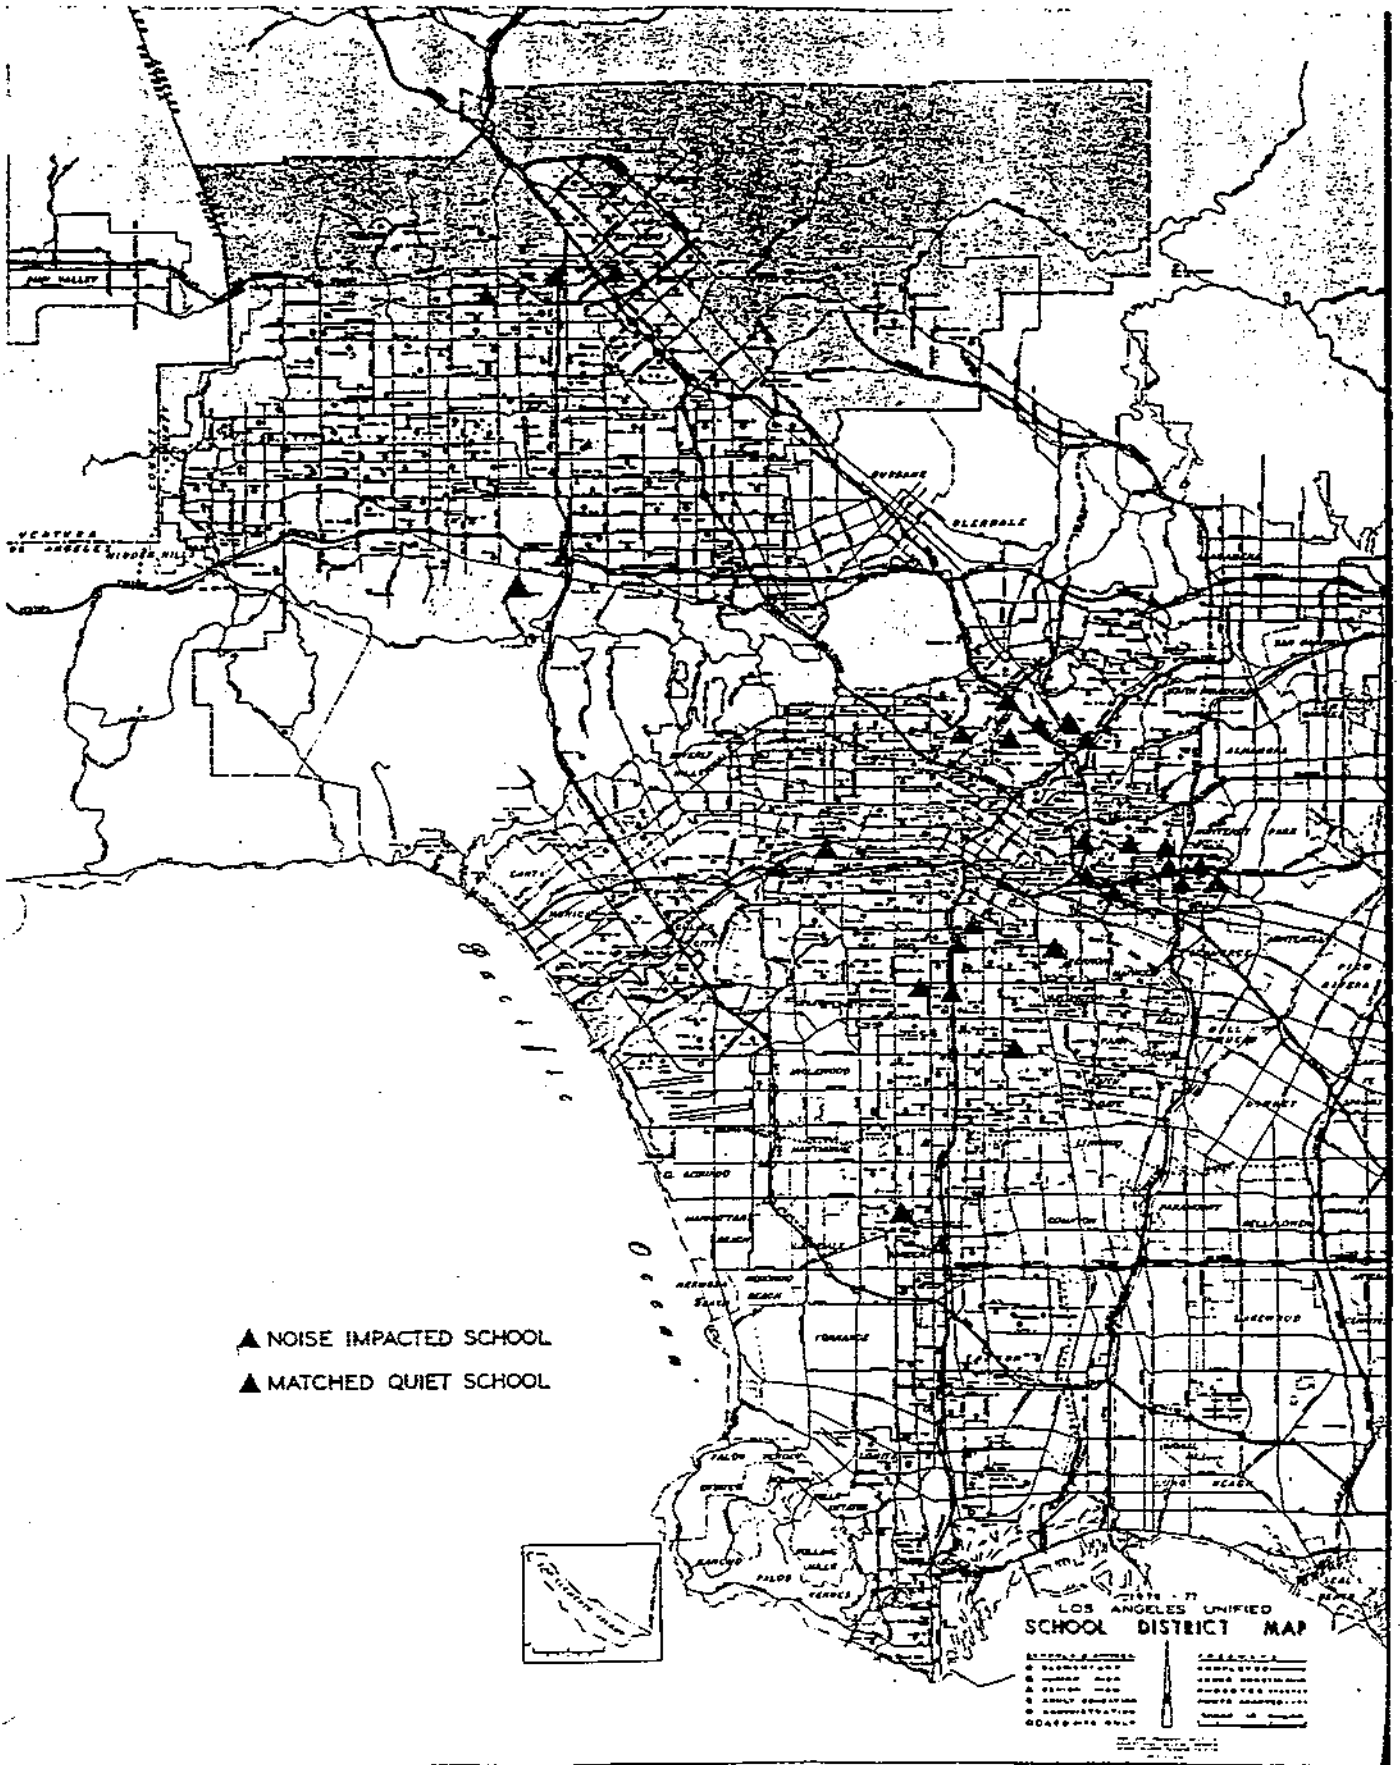

- DETERMINE CORRELATIONS BETWEEN ENVIRONMENTAL NOISE LEVELS, CHILDRENS' EXPOSURE LEVELS, HEARING LOSS AND ACADEMIC ACHIEVEMENT.
- DETERMINE THE DEGREE TO WHICH ENVIRONMENTAL NOISE MAY IMPEDE THE CLASSROOM PERFORMANCE OF TEACHERS AND STUDENTS.
- DEVELOP AN EMPIRICALLY BASED INTERIOR NOISE INTRUSION STANDARD FOR SCHOOL CLASSROOMS.

Appendix E

**Statement by Teacher for
Recording Normal Voice Level**

My name is (*state in full - e.g., Mrs. Harriet von Hobson*). This is Room (*No.*) and the (*Number*) grade. This recording is to obtain a sample of the loudness of my voice. I normally speak to my entire class at this intensity.

Appendix F

Criteria for Use of Buttons During Classroom Observations

Note: All buttons must be held down for 1 second or more to insure an adequate electronic response.

Button Number

1. **Disregard:** Is for any event that is caused by "normal" sounds in the classroom. For example, school bell, paging a child or teacher over the school's intercom, visitors, library carts, etc.

Note: Children calling outside the classroom should not be a Disregard, particularly if such noise is distracting. Rather, it should be a Distract or Interrupt button.

Note: When any of the other buttons are pressed as a result of some internal (classroom) noise event, Disregard should be pushed immediately after releasing the other button in order to discriminate between external and internal noise events. On occasion this sequence was not followed; determination of the cause of "Can't Hear" or other event was discerned by listening to the tape.

Note: Fire and earthquake drills should be noted on written record.

2. **Can't Hear:** Is to be used when the observer is not able to hear and understand the teacher or student. The observer should use ears, not eyes, for this button - that is, do not attempt to lipread (the study is trying to estimate the percentage of time information cannot be heard or understood).

If the observer is unable to hear about 5 words or less, do not use Can't Hear button. If the observer is unable to hear or understand 6 or more consecutive words, push Can't Hear and hold until able to hear and understand. If unable to hear and press Can't Hear and the voice level increases, release Can't Hear and push Raise. Short answers (5 words or less) to questions that are not heard, for example, should be marked "Can't Hear".

3. **Rebuke:** Is to be used when the teacher calls the class or several individual students to order with or without a raised voice level. If noise was the cause, it should be possible to discern that from listening to the tape. Rebuke can be pushed as frequently as necessary, and should be held down until the class returns to order. Rebuke will vary with the teacher's particular style and will generally be of short duration. It may be: "Johnny!", "I'm waiting for quiet!", "I need attention!", etc. It may be silent - taking the child by the arm and walking to the hallway or outside the room.

4. **Interrupt/Pause:**

Interrupt: A 1-second press is to be used if the teacher or student stops an activity (talking, writing or reading) due to noise, and resumes the activity after the noise stops. The noise may be either internal or external in origin. The source of noise may be the freeway, airplane, helicopter, bus, fire truck, siren, etc.

Pause: Is 2 1-second presses to indicate a non-noise event, such as a student with a note from the office, a child being put in the hallway for discipline, students leaving to go to work in the cafeteria, etc. Use only if there is an obvious cessation of classroom activity.

5. **Distract:** Should be used in response to some external or internal event. When the children look around, fidget, or in some way lose their concentration, the Distract button should be pressed down and held for as long as necessary. Distract may be the result of a visitor - parent, teacher, principal, nurse, etc., entering the room. It may also be a loud or unusual noise from any source such as screech of brakes, freeway accident, car or truck "backfire", chair tipping over, microphone tipping over, breaking glass, etc. (N.B.: This event was observed very infrequently.) Distract may be followed by Rebuke.
6. **Raise** Is used if the teacher or student increases voice intensity. The increase may be in response to an increase in noise level from an internal or external source. It may be because one person is trying to get attention, children out for recess, or an increase in other external noise sources. Raise may be used after the fact and it is likely to be used that way. For example, voice level increases slowly, and consequently it may require some time before the voice level increases to the point the observer notices. When the teacher calls a single name at an increased level, push Rebuke rather than Raise. (N.B.: This event was almost never due to noise, rather it was associated with a "Rebuke".)
7. **Start/Stop:** To start an activity (recording period), push a variable number of times.

Aircraft Noise and Children: Longitudinal and Cross-Sectional Evidence on Adaptation to Noise and the Effectiveness of Noise Abatement

Sheldon Cohen
University of Oregon

David S. Krantz

the Health Sciences

Gary W. Evans
University of California at Irvine

Daniel Stokols and Sheryl Kelly
University of California at Irvine

Longitudinal and cross-sectional data on effects of aircraft noise on elementary school children are presented as evidence for the effects of community noise on behavior. To examine the generality of previous laboratory findings in a naturalistic setting, the study assesses the impact of noise on attentional strategies, learned helplessness, performance on cognitive tasks, and blood pressure. Children were tested on the same measures twice, with a 1-year interval between sessions. A previous article reported cross-sectional findings from the first testing session. In the present article, longitudinal data are used to determine whether children *adapt* to the aircraft noise over the 1-year period and to assess the effectiveness of noise abatement interventions introduced in a number of noise-impacted classrooms. Additional cross-sectional data from the original testing session are also presented to provide further information on the utility of noise abatement. In general, there was little evidence for adaptation to noise over the 1-year period. Noise abatement had small ameliorative effects on cognitive performance, children's ability to hear their teachers, and school achievement. The implications of the study for understanding the relationship between noise and behavior and resulting policy implications are discussed.

Although prolonged exposure to high-intensity noise can cause temporary and permanent losses of hearing (cf. Kryter, 1970), other general statements about the debilitating effects of routine noise exposure have to be made with considerably less confi-

dence. It is, of course, difficult to isolate the effects of a particular characteristic of a natural environment on the health and behavior of its occupants. Invariably the possibility exists that the people who choose (or are forced) to work or live in a noise-impacted environment are somehow different than those who work or live elsewhere. Moreover, environments that suffer from high levels of noise often have other characteristics (e.g., pollution, poor housing, high levels of population density) that may also deleteriously affect behavior and health.

The research reported in this article was supported by grants from the National Science Foundation (BNS 77-08576 and SOC 75-09224), the National Institute of Environmental Health Sciences (1 RO1 ESO176401 DBR), the Society for the Psychological Study of Social Issues, the University of Oregon Biomedical Fund, and the Uniformed Services School of Medicine (Clinical Investigation Grant 7208).

The authors are indebted to Laura Martin, Laurie Poore, Robyn Dawes, Jerry Lukas, Rich Haller, Ray Hyman, Nick Garshnek, the administrative staff, teachers, children, and parents of participating schools; the California Assessment Program; and the California Department of Health. We also wish to thank Michael Posner and Myron Rothbart for comments on an earlier draft.

Requests for reprints should be sent to Sheldon Cohen, Department of Psychology, University of Oregon, Eugene, Oregon 97403.

In a recent article, Cohen, Evans, Krantz, and Stokols (1980) argue that the impact of noise (and other environmental factors) on health and behavior can best be assessed by a methodological strategy that combines the use of laboratory (experimental) and naturalistic studies. Laboratory studies direct our attention to categories of behavior and health that may be affected by noise and establish a causal link between noise and

these behaviors. Naturalistic research helps to establish whether particular effects found in the laboratory also occur in real-life settings. Cohen et al. (1980) argue that an interplay between these two approaches provides a more complete understanding of the relationship between environmental stressors and behavior and generates the type of data necessary to influence public policy.

Recent laboratory research on the impact of high-intensity noise has directed attention to the possible effects of community and industrial noise on a number of nonauditory systems. For example, noise is associated with alterations in task performance (cf. Broadbent, 1978; Loeb, 1979), decreased sensitivity to others (e.g., Cohen & Lezak, 1977; Mathews & Canon, 1975), and elevation of a number of nonspecific physiological responses (cf. Glass & Singer, 1972; Kryter, 1970). Exposure to noise that is unpredictable and uncontrollable can also result in *aftereffects*—deficits in performance and social sensitivity that occur after the noise is terminated (e.g., Glass & Singer, 1972; also see review by Cohen, 1980). The difficulty with this research is that it emphasizes acute rather than long-term noise effects. Thus, its implications for those suffering prolonged exposure in their homes or at work are unknown.

Although investigators have also begun to take a closer look at the nonauditory effects of noise in naturalistic settings (see reviews by Cohen, Glass, & Phillips, 1979; Kryter, 1970; Miller, 1974), methodologically tight studies are rare. This research also tends to be atheoretical and thus difficult to compare with existing laboratory work. Moreover, there are few *longitudinal* studies of people living and/or working under noise. Thus, it is unknown whether prolonged noise exposure results in increasingly deleterious effects or whether those exposed for prolonged periods adapt to noise, with effects disappearing after awhile. Studies comparing measures of health and behavior of the same person before exposure, immediately after exposure begins, and at set intervals for 1 or several years would allow us to determine the long-term course of stress and adaptation. In addition, longitudinal studies in situations in which the environmental stressor

is removed or attenuated would make it possible to determine whether there are long-term aftereffects of prolonged noise exposure.

Accordingly, this article reports data from the Los Angeles Noise Project—a longitudinal study of the impact of aircraft noise on elementary school children. The study was designed to examine the course of adaptation and the impact of a noise-abatement intervention on a variety of physiological, cognitive, and motivational measures. It is particularly concerned with exploring the generality of laboratory work on noise-induced shifts in attentional strategies, feelings of personal control, and nonauditory physiological responses related to health. (Findings from noise-induced laboratory exposure are discussed more fully in Cohen et al., 1980).

In this study elementary school children living and attending school under the air corridor of a busy metropolitan airport were compared with a matched group of children living in relatively quiet neighborhoods. In an earlier article, Cohen et al. (1980) reported cross-sectional data indicating that children from noisy schools had higher systolic and diastolic blood pressures than those from matched control schools and that this difference was greatest in children with the fewest years of exposure. Noisy-school children were also more likely to fail on a cognitive task and more likely to "give up" before the time to complete the task had elapsed. Finally, children from noisy schools who had lived in the neighborhood less than 2 years were less distractible than their quiet-school counterparts, whereas those children living under noise for more than 4 years were more distractible than those from quiet schools.

As part of a settlement of a law suit brought by the school systems against the airport, money was made available to lower the interior sound levels of many of the schools in the landing corridor. During the summer following the collection of data for the Cohen et al. article, architectural interventions were instituted in 43% of the noisy-school classrooms. These interventions resulted in a substantial decrease in noise levels in treated rooms (data presented later).

Thus, a large number of noisy-school children spent the following school year in noise-abated classrooms. At the end of the school-year (1 year after original testing), children who were still enrolled in their schools (noisy and quiet) were retested on the original measures.

This article uses these longitudinal data and some previously unreported cross-sectional data from the first testing session to answer two questions about the long-term impact of aircraft noise on elementary school children. First, do children retested 1 year later continue to show effects found during the first testing session or do they *adapt* to the noise over the 1-year period? Cross-sectional data reported in the earlier article found some evidence for decreasing effects suggestive of physiological (blood pressure) habituation as duration of exposure increased, but failed to indicate adaptation of annoyance, cognitive performance, or helplessness. Second, what are the effects of noise abatement interventions in the classrooms on the various measures of health and behavior? That is, does assignment to a quieter classroom ameliorate the effects of noise?

Method

Overview of the Study

The subjects were children attending the four noisiest elementary schools in the air corridor of Los Angeles International Airport and three control (quiet) schools with similar (matched on social class and race) student bodies. Peak sound level readings in the noise schools are as high as 95 dB (A), and the schools are located in an air corridor that has over 300 overflights a day—approximately one flight every 2½ min. during school hours (Lane & Meecham, 1974). The study focuses on effects occurring *outside* of noise exposure. Thus, all tasks and questionnaires (except the achievement test records gathered from school files) were administered in a quiet setting—a noise-insulated trailer parked directly outside the school. Students were tested first in the spring of 1977 (T1) and again in the spring of 1978 (T2).

Tasks administered during the test periods were designed to assess feelings of personal control and to determine whether the children employed some common attentional coping strategies. Children were also asked a number of questions about their response to home and classroom noise and had their blood pressures measured. At the time of the first (but not the second) testing session, a parent questionnaire dealing with parent response to noise, mother's, and father's level of education, and the number of children in the family was sent home

with each child. Scores on standardized reading and math tests and data on absenteeism were also collected from school files at the time of the first (but not the second) session.

Data from subjects who were tested at both testing sessions (longitudinal data) were analyzed to determine if noise effects adapted—decreased or disappeared—over the 1-year interval between sessions. Separate analyses (both cross-sectional and longitudinal) were conducted to evaluate the effectiveness of the noise-abatement interventions. The cross-sectional data were collected during the first testing session and compared children who were in noise-abated classrooms with those in noisy (nonabated) rooms as well as those who were from quiet schools. The longitudinal analyses looked at the changes in the response of children who moved from a noisy to a noise-abated classroom in contrast to those children who spent both years in noise-impacted rooms.

This section will provide brief descriptions of the experimental tasks and procedures. The reader is referred to Cohen et al. (1980) for additional detail.

Matching

Three control schools (quiet schools) were matched with the experimental schools for grade level, ethnic and racial distribution of children, the percentage of children whose families are receiving assistance under the Aid to Families With Dependent Children program, and the occupations and educational levels of parents. (Detailed data on matching are reported in Cohen et al., 1980). Thus, we were able to compare samples of children attending noisy and quiet schools who were relatively similar in terms of age, social class, and race. A regression analysis procedure (described later) allowed additional control over these factors.

Subjects

The study included children from all noise-impacted third- and fourth- grade classrooms in each noisy school as well as children from an equivalent number of classrooms in quiet schools. To assure that performance differences between children from noisy and quiet schools could not be attributed to noise-induced losses in hearing sensitivity, children failing (either ear) an audiometric pure tone threshold screening (500, 1000, 2000, 4000 Hz at 25 dB) were not included in the study. Six percent of the noisy-school and 7% of the quiet-school children failed the screening.

Noise Measures

Testing session 1: Interior sound levels (without children) were measured inside each classroom with Traoustics Sound Level Meters (SLM S2A). Peak decibel level (A scale) was recorded during 1-hour sessions in both the morning and afternoon. It is important to note that due to limitations in the equipment and duration of the measurement, these measures are presented only to establish *relative* differences between the sound levels of various types of classrooms, not as evidence for sound-level criterion or threshold levels of effects.

Testing session 2: Sound levels (again without chil-

dren) were measured inside each classroom for 1 hour during the morning and 1 hour during the afternoon with Digital Acoustics (DA605), B and K (4426), and General Radio (1945) noise-level analyzers.¹ The machines were calibrated to a pure tone source every other day and were periodically calibrated against one another to ensure intermachine reliability. Microphones were placed approximately 3 feet (.9 m) from the ground in the center of the room. Data available from all machines included peak decibel level (A scale), the decibel level exceeded 33% of the time (L_{33}), and the noise level averaged on an energy basis over each hour period (L_{EQ}).

Parent and Child Questionnaires

The questionnaire administered to each child assessed his/her perception of classroom and home noise levels. The parent questionnaire (T1 only) also included questions on perception of home noise level as well as queries as to how long the child had been enrolled in his/her school and how long she/he had lived at the present address. Data on school enrollment were also available from school files.

Blood Pressure and Health

Each child's resting blood pressure (systolic and diastolic) was taken each testing day on an SR-2 Physiometrics automated blood pressure recorder.² Blood pressure data are based on the mean systolic and diastolic pressures for these two measurements. The graphic output of the machine was coded after the study was completed, with coders blind to experimental condition. Each child's height and weight were also measured. Absenteeism was used as an indirect measure of health, since absence from school is often attributable to illness. These data were available from school files.

Helplessness

Performance on a cognitive task preceded by a success or failure experience was employed to examine the effect of noise on response to failure and on persistence on a difficult task. Response to failure is a standard measure of susceptibility to helplessness (cf. Seligman, 1975). Thus, if noisy-school children are more susceptible to helplessness, they will show greater effects of a failure experience than their quiet-school counterparts. A lack of persistence ("giving up" syndrome) is considered a direct manifestation of helplessness.

First testing session. Each child was given a treatment puzzle to assemble after the tester demonstrated the task with another puzzle. One half of the children received an insoluble (failure) puzzle and one half a soluble (success) puzzle. The soluble puzzle was a circle, and the insoluble puzzle was a triangle. After time (2½ min.) was up on the first puzzle, the child was given a second, moderately difficult puzzle to solve. The second (test) puzzle was the same—a square—for all (success and failure) children. The child was allowed 4 min. to solve the second puzzle. Whether the puzzle was solved, how long the solution took, and whether the child "gave up" before the 4 min. had elapsed were used as measures of helplessness.

Second testing session. Treatment puzzles were not readministered during the second session. Each child was given only the test (square) puzzle to solve. As previously, the child was allowed 4 min. to solve the test puzzle, with the same measures of helplessness assessed as in the earlier testing session.

During T1, a large proportion (34%) of the children assigned to the success condition who received a soluble treatment puzzle failed to solve the treatment puzzle within the 2½ min. allowed. Although the fact that a number of children self-selected themselves into a failure condition makes it difficult to interpret main effects for success-failure and interactions between success-failure and noise, comparisons between the children from noisy and quiet schools, irrespective of (controlling for) their pretreatment, are of primary interest.

Distractibility

It was proposed in our earlier article (Cohen et al., 1980) that children reared in noisy environments become inattentive to acoustic cues (cf. Cohen, Glass, & Singer, 1973; Deutsch, 1964). Since children who are relatively inattentive to acoustic cues should be less affected by an auditory-distractor, distractibility was used as a measure of this selective inattention. Subjects performed a crossing out *Es* task under both ambient and distracting conditions. The subject's task was to cross out the *Es* in a 2-page passage from a sixth-grade reader. Each subject worked on a short practice paragraph and then on the task for 2 min. Two versions (different samples of prose) were used.

In a distraction condition, the child worked on one of the versions of the task while a tape recording of a male voice reading a story was presented at a moderate volume over headphones. In the no-distraction condition, the alternative form of the task was completed with headphones on but under ambient sound conditions. The distraction and no-distraction tasks were administered on different testing days. Both the order of alternative versions of the task and the experimental conditions were counterbalanced. The criterion measure was performance (percentage of *Es* found) on the distraction task after these scores were adjusted for no-distraction performance. It was expected that children from noisy schools would be less affected by distraction.

¹ The noise-level analyzers, which were not available to us during the first testing session, were used during the second session because of their increased sensitivity and accuracy and their ability to provide various measures of noise over time, for example, L_{EQ} and L_{33} . It is, however, appropriate to again caution the reader that the rather short interval of measurement limits the use of these data to the establishment of relative sound levels of classrooms in the various conditions.

² This instrument is an electronic infrasonic device that records on a rotating paper disc. Measurements were taken with a rubber cuff entirely encircling the upper arm. The reliability of this device for blood pressure measurement in children has been established in previous work (e.g., Voors, Foster, Frerichs, Weber, & Berenson, 1976).

Table 1
Overview of the Analyses

Title of analysis	Sample	Classroom noise condition		Additional independent variable/conditions
		1977 (T1)	1978 (T2)	
I. Attrition bias	T1	Noise vs. quiet		Retested at T2? Yes No
II. Adaptation to noise	Attrition (T1 & T2)	Noise ^a ——— Noise		None
		vs.		
		Quiet ——— Quiet		
III. Blood pressure: Habituation or attrition?	T1	Noise vs. quiet		Migration Not enrolled in school 1 year after T1 vs. Enrolled in school 1 year after T1 but not 2 years later vs. Still enrolled 2 years after T1
IV. Noise abatement: Cross-sectional analyses	T1	Noise vs. abated vs. quiet		None
V. Noise abatement: Longitudinal analyses	Attrition (T1 & T2)	Noise ——— Noise		None
		vs.		
		Noise ——— Abated		

^a The few classrooms that had had noise-abatement work completed prior to T1 are included as noisy classrooms in these analyses. This was done in order to make these analyses comparable to those reported in Cohen et al. (1980) and is justified by the findings reported in this article suggesting little if any effect of abatement.

School Achievement

The scores on the California Test of Basic Skills (California Assessment Program, 1976) reading and math tests (administered during the second and third grades by the school system) were gathered from school files, and the Wepman (1958) auditory discrimination test was administered individually to children in the soundproof van. The Wepman test measures the child's ability to discriminate between pairs of words that differ from each other in either initial or final sound, for example, "sick-thick" or "map-nap."

To roughly equate the effect of the noise and quiet conditions on the aptitude of the children at the time they entered school, analyses of school achievement and auditory discrimination scores included an additional control for the mean cognitive abilities (standardized test administered by school) of the child's class on entering the first grade.

Analyzing and Interpreting Data

The answers to our questions about adaptation to noise and abatement effectiveness each require different blockings (or groupings) of the noise variable and analyses of different subsets of the sample. Table 1 provides an overview of these analyses. It may be useful for readers to refer to this table while reading the results sections of the article.

To avoid confusion about exactly which analysis and/or data set is being employed at any point, we will present two consecutive sets of results and discussions. The first will examine the question of adaptation and the second the question of the effectiveness of the noise-abatement interventions. These sets will be followed by a short section on the overall implications of the study.

The general statistical model (described below) was used in all data analyses reported in this article. Biases in subject attrition (also described below) are important in aiding interpretation of all longitudinal analyses. Attrition bias is not an issue in the interpretation of cross-sectional analyses, which involve only T1 data and thus include the entire T1 sample.

Statistical analyses. A regression technique was used in all the analyses reported in this article to allow additional control over the effects of socioeconomic and demographic factors (cf. J. Cohen & Cohen, 1975). All data analyses include controls for the number of children in the child's family, grade in school, months enrolled in school, and race. These control factors, forced into the regression first, are then followed by noise, and then the interaction between noise and months enrolled in school.³ Additional controls are used in the analyses of

³ To avoid confusion, the reader should note that two distinct terms are used to refer to different time frames. T1 and T2 refer, respectively, to the first and second testing sessions, separated by 1 year. The term "months

blood pressure (height and ponderosity), school achievement (cognitive aptitude test), and distractibility (performance under ambient conditions). The primary helplessness analyses include factors for success-failure and the interaction between success-failure and noise. (Those who solved and those who did not solve the success treatment puzzle are treated as separate groups.) Analyses of longitudinal data also include a repeated measure factor (Testing Session 1, Testing Session 2).⁴ School achievement analyses were performed with classrooms (nested in noise) rather than with individual children, as the unit of analysis. A more detailed description of the form of each analysis is provided in Cohen et al. (1980).

The various measures were analyzed in predetermined multivariate clusters created on the basis of theoretical consideration.⁵ This form of analysis helps to decrease the probability of chance findings that occur when a large number of analyses are necessary (cf. Bock, 1975).

Interpreting longitudinal analyses: Sample attrition bias. An effort was made to retest all students who were attending school during the longitudinal follow-up. Sixty-two percent (163: 83 noise and 80 quiet) of the original sample (262: 142 noise and 120 quiet) were retested. Although a slightly higher proportion of quiet (67%) than noisy (58%) school children were retested, this difference was not statistically significant, $\chi^2(1) = 1.99, p < .16$.

All data analyses that include data from the second testing session (these are all repeated measures designs) were based on the 163 retested students—the *attrition sample*. Sample attrition (not being retested) may be attributable to either migration or absenteeism. It is our purpose at this point in the article to describe the nature of any self-selection bias in the retest sample; thus, these causes of attrition are not separated.

The purpose of the attrition bias analyses was to determine whether remaining in the study (being retested) was correlated with one or more of the criterion variables in one of the study's conditions (noise or quiet) but not in the other. For example, noisy-school children who were *not* retested had higher blood pressures than those who were retested; whereas being retested was unrelated to blood pressure for quiet-school children. This particular attrition bias resulted in a deflated mean blood pressure for noisy-school children in analyses of the attrition sample. As a result, there is a lessening of the difference between mean blood pressures of noisy- and quiet-school children. It is important to note cases in which the lack of a main effect for noise in the attrition sample is due to selective attrition as opposed to adaptation to noise or problems with measure reliability. To determine whether any such biases occurred, data from the first testing session (all of the original 262 subjects) were analyzed with whether a student was retested (yes/no), and a Retest \times Noise interaction added to the standard analysis (see Table 1, I). Note that these analyses are not presented in an attempt to make any conclusions about those who were retested versus those who were not but only to provide information about the nature of the attrition bias that may be useful in interpreting anal-

enrolled in school" refers independently to the length of time the child was enrolled in school at T1.

yses presented later in this article. For this reason, a rather liberal alpha level (.10) was employed, and multivariate analysis is not reported.

A retest bias occurred on a number of the dependent variables. On all of these variables, those in the noise condition who showed the greatest stress during T1 were not present at T2. No such relationship (or in some cases a slight reversal) existed in the quiet group. The variables with Noise \times Retest interactions suggesting this pattern were the child's perception that noise made it difficult to hear their teacher, $F(1, 241) = 3.46, p < .06$, and systolic, $F(1, 233) = 8.65, p < .004$, and diastolic, $F(1, 233) = 3.39, p < .07$, blood pressure.

Adaptation to Noise

Results

To determine whether or not the children adapted to the noise over the 1-year period, data from the attrition sample (those who were tested at both T1 and T2) were analyzed in a repeated measures design, with Testing Sessions 1 and 2 constituting the repeated measure (see Table 1, II). The occurrence of the same difference between noise and quiet schools at both T1 and T2 (main effect for noise) provides evidence for test-retest stability. A diminution of the T1 difference between noise and quiet at T2 (Noise \times Testing Session interaction) suggests the possibility of progressive adaptation to the noise stressor. Finally, an increased difference between noise and quiet at T2 (Noise \times Testing Session interaction) suggests that increased exposure results in an increased effect of noise.

It is important to note that these analyses include only the attrition sample (163), that is, those who were enrolled and present during the second testing session. Thus, vari-

⁴ Two new variables, sum (T1 + T2) and difference or change score (T1 - T2), were created for each dependent variable. Then separate regression analyses were conducted on each of the new variables. Analyses of the sum score reflect differences between groups, irrespective of the testing session, whereas analyses of change scores reflect differences between testing sessions over groups. The results of these analyses are mathematically equivalent to a standard repeated measures analysis with two levels of the repeated measure (cf. Overall & Klett, 1972).

⁵ There are separate clusters for general health, blood pressure, helplessness, and the child questionnaire. The distraction analyses were run as univariates, since each analysis required a unique control factor.

ables that were related to attrition for noisy-school (but not quiet-school) children, including the child's perception of classroom noise and the blood pressure measures, are unlikely to show noise effects in this analysis.

Children's perceptions of noise. Main effects of noise for children's reports of how much airplane noise bothered them at home, $F(1, 145) = 3.62, p < .05$, and in the classroom, $F(1, 145) = 15.74, p < .001$, suggest that those attending noisy schools report high levels at both testing sessions. There was no effect on the remaining child questions. The multivariate noise effect was significant, $F(7, 139) = 3.13, p < .004$.

These results are generally consistent with those reported in the original study (analyses including the entire sample of children tested at T1) in which noisy-school children reported noisier classrooms (a variable affected by attrition bias in the present analysis) and said that airplane noise bothered them more in both home and classroom.

Health measures. Although neither height nor weight were significantly related to noise in the entire T1 sample, noisy-school children did attend school more often than their quiet-school counterparts. In the present analysis, there was a Noise \times Testing Session effect for the percentage of days attending school, $F(1, 120) = 8.00, p < .005$. Although noisy-school children had better attendance during the year of the first testing session (98% attendance for noise group versus 96% for quiet), the attendance of noisy- and quiet-school children was equivalent (94% for both groups) during the following year. The multivariate for the interaction effect of Noise \times Testing Session was significant, $F(3, 118) = 3.71, p < .01$.

Blood pressure. Although the analysis of the complete T1 sample indicated inflated systolic and diastolic blood pressure for noisy-school children, there were no effects of noise, testing session, or any of the interactions on either systolic or diastolic blood pressure in the present analysis. Longitudinal blood pressure effects were not expected, however, since a relatively high proportion of noisy-school children with high blood pressure were lost to attrition and thus were not included in the present analyses.

Distractibility. In the earlier report of

Figure 1. Distractibility at T1 and at T2 as a function of school noise level and duration of exposure. (Each period on the number of year's of exposure coordinate represents one quarter (based on quartiles) of the sample. For example, 25% of the sample were enrolled in school for less than 2 years.)

the entire T1 sample (Cohen et al., 1980), an interaction was found between noise and months enrolled in school for the percentage of Es found on the distraction task. Children in noisy schools did better than the quiet group on the distraction task during the first 2 years of exposure and worse after 4 years. Quiet- and noisy-school children who had been enrolled between 2 and 4 years, demonstrated equivalent performance. As apparent from the lower half of Figure 1, the attrition sample showed a similar T1 pattern, except that noisy-school children, who had been enrolled for 2-4 years also appeared to be less distractible than their quiet-school counterparts. Examination of the upper half of Figure 1 indicates that the T2 sample continues to show the same pattern of better performance by the noise group on the distraction during the earlier years. In this case, however, performances of the noisy-school and quiet-school groups are rather equivalent after 4 years of enrollment—Noise \times Months interaction, $F(1, 141) = 3.66, p < .06$.

Helplessness. As in the analysis of the entire T1 sample, there are effects of noise on test puzzle performance that occur irre-

spective of whether the child received a success (solved or not) or failure treatment. Noisy-school children were more likely to fail the test puzzle than quiet-school children, $F(1, 133) = 5.37, p < .02$, and more likely to take longer solving the puzzle, $F(1, 133) = 2.88, p < .09$, than quiet-school children—multivariate effect for noise, $F(3, 133) = 1.92, p < .12$. Although differences between proportion of children failing and time to solution were stable across the two testing sessions, quiet/noise differences in the percentage of children giving up occurred only at T1—Noise \times Testing Session interaction, $F(1, 133) = 3.90, p < .05$. The multivariate effect for the Noise \times Testing Session interaction was not, however, significant, $F(3, 131) = 1.57, p < .20$.

As pointed out in Cohen et al. (1980), an analysis of the proportion of children giving up that includes only those children who failed the test puzzle provides the most direct measure of helplessness. This analysis looks at the degree to which failure is associated with giving up as opposed to unsuccessful persistence. Although data for the entire T1 sample indicated increased giving up on the part of noisy-school as opposed to quiet-school children, there was neither a noise nor Noise \times Testing Session interaction in the present analysis.

Although not directly relevant to problems posed in this article, it is of general interest to examine whether the soluble or insoluble puzzle given at T1 affected performance on the test puzzle administered 1 year later, irrespective of (i.e., controlling for) noise exposure. This comparison provides a rough measure of the duration of the learned helplessness effect. That is, does a failure as opposed to a success pretreatment affect subsequent task performance as much as a year later? As suggested earlier, because of a selection bias created by subjects who were assigned to a soluble puzzle condition who failed to solve their soluble puzzle, there were three levels of the success-failure factor: success group who solved their pretreatment puzzle, success group who failed their pretreatment puzzle, and failure group. At both T1 and T2, children who received a success treatment puzzle and solved that puzzle were more likely to solve, $F(2,$

133) = 5.39, $p < .006$, and faster at solving the test puzzle, $F(2, 133) = 3.16, p < .05$, than both those who failed to solve the success treatment puzzle and those who received a failure treatment puzzle. There were no differences between these conditions on the proportion of children giving up; multivariate for success-failure, $F(6, 262) = 2.16, p < .05$. These data suggest the possibility of a helplessness effect persisting over a 1-year period, but they are difficult to interpret because of the self-selection problem.

Discussion

In general, the retest data provide strong support for the stability of the effect of noise on annoyance, distractibility, and performance on a moderately difficult task. First, at both testing sessions, noisy-school children were bothered more by aircraft noise than quiet-school children in both the classrooms and homes. Second, the similarity of the T1 and T2 data on the distraction task suggests the relative stability of this unpredicted interaction. Specifically, it suggests that there is some initial increased ability among noise-impacted children for "tuning out" auditory distraction and that this advantage disappears after 4 years of exposure. It was suggested in the earlier article that the children initially attempt to cope with the noise by tuning it out. Later, however, as they find that the strategy is not adequate, they give it up. An alternative explanation is that as duration of exposure increases, the children become more discriminating in terms of the kinds of sounds that they tune out. That is, initially they tune out wide range of acoustic stimuli (including the distractor used in the present study, which is dissimilar to aircraft noise), but later they tune out only sounds that are similar to the aircraft noise.

The present analyses also suggest that noisy-school children were poorer than quiet-school children at solving the test puzzle at both testing sessions. However, the increased "giving up" on the part of the noisy- as opposed to quiet-school children found in the analysis of the entire T1 sample was not found in the present analysis. The lack of

such an effect may have occurred because of subject attrition, because the children had had a previous experience with the same puzzle, or because the effect disappeared, that is, adapted out over time. It should be noted that the cross-sectional analysis of the entire T1 sample *did not* indicate a lessening of giving up with increased months of school enrollment. This suggests that the giving up effect does not adapt out over time.

Although the previously reported differences between the noisy- and quiet-school children on systolic and diastolic blood pressure were not found in the analysis of the attrition sample, this result was expected, given the large proportion of noisy-school children with high levels of blood pressure who were not retested. Because of this, the lack of a relationship between noise and blood pressure (at either T1 or T2) in the attrition sample *does not* constitute information for the acceptance or rejection of the hypothesis that the children adapted to noise.

A piece of data that was rather inconsistent with other findings in the original study of the entire T1 sample was that noisy-school children attended school more often than quiet-school children. The present data suggest that this difference did not exist for the data collected at T2. We are unable to explain the difference that occurred at T1 and feel that it may reflect random fluctuation, with T2 reflecting a regression to the mean.

In sum, the data suggest that effects related to living and attending school in a noisy neighborhood are stable over a 1-year period. That is, there is little evidence for adaptation to the noise.

Blood pressure: Habituation or attrition? The cross-sectional analysis of the entire T1 sample reported in an earlier article (Cohen et al., 1980) similarly found little evidence for adaptation. In fact, the only data supporting an adaptation hypothesis was the finding that systolic blood pressure differences between noisy- and quiet-school children (noisy-school children had higher blood pressure) were greater during the first few years of school enrollment. A similar pattern also occurred for diastolic pressure, although it did not reach statistical significance. (Figure 2 depicts the results of

Figure 2. Systolic and diastolic blood pressure as a function of school noise level and duration of exposure. Each period on the number of years of exposure coordinate represents one quarter (based on quartiles) of the sample. For example, 25% of the sample were enrolled in school for less than 2 years. (From "Physiological, Motivational, and Cognitive Effects of Aircraft Noise on Children: Moving from the Laboratory to the Field" by Sheldon Cohen, Gary W. Evans, David S. Krantz, and Daniel Stokols, *American Psychologist*, 1980, 35, 231-243. Copyright 1980 by the American Psychological Association. Reprinted by permission.)

the T1 sample analysis, as reported in Cohen et al., 1980.) As previously suggested, this effect could be due to noisy-school children adapting to the stressor as the duration of exposure increased. On the other hand, the effect could be due to some kind of subject selection bias. That is, children with noise-induced, elevated blood pressure may have quickly moved out of the noise-impacted neighborhood and thus lessened the mean blood pressure for noisy-school children in the 2 or more years of exposure categories.

Some longitudinal data on how long specific noisy- and quiet-school children remain enrolled in their schools can help distinguish between these two explanations. The attrition bias analyses reported earlier suggest the possibility that people who move out of noise-impacted neighborhoods are different than those who move out of similar neighborhoods not suffering from noise pollution. Conclusions of this kind cannot, however, be

made from the attrition analyses, since a subject assigned to the not-present-during-retesting category may have moved or may have merely been absent during the retesting session. Thus, a second analysis of T1 blood pressure data was conducted to determine whether families of noisy-school children who showed elevated blood pressure were more likely to *move* sometime during the 2 years following the original testing session than families of quiet-school children and of noisy-school children not showing elevated pressure. In this case, unlike the attrition analyses, children who were absent at T2 but still enrolled were categorized as attending school. The retest factor used in the attrition analysis was replaced with a three-level measure of *migration* (not enrolled in school after 1 year/enrolled 1 year later but not after 2 years/still enrolled after 2 years, see Table 1, III).

As in the attrition bias section, we are concerned primarily with the Noise \times Migration interaction. This interaction suggests that those children leaving the noise-impacted neighborhood have different scores on blood pressure than those leaving the quiet neighborhood. As depicted in Figure 3, noisy-school students with the highest blood pressures move out of the noise area soon (within 2 years) after the initial testing: $F(2, 229) = 6.80, p < .001$, for systolic, and $F(2, 229) = 3.50, p < .03$, for diastolic. The multivariate interaction effect was significant, $F(4, 456) = 3.84, p < .004$. Thus, it appears that selective attrition, *not* adaptation, is responsible for the decrease of the difference between the blood pressure of noisy-school and quiet-school children.

Apparently the families of those noise-group children who showed elevated blood pressure were more likely to move out of the noise-impacted neighborhood than the families of children who did not show elevated blood pressure. It is important to emphasize that these effects occurred with race and social class partialled out of the analyses and that this bias for those with higher blood pressure to move out of the neighborhood occurred only in the noise-impacted area. Some possible explanations for this effect are that (a) parents of children with elevated blood pressure were sensitive to their chil-

dren's experience of stress and as a consequence moved to a less noisy neighborhood; (b) because of a familial bias (either genetic or environmentally determined), parents of children with noise-induced blood pressure elevations experienced similar stress-related reactions that motivated them to move from the neighborhood; (c) the children's elevated blood pressures were a response not to the noise itself but to their parents' own noise-induced stress, which was motivating the parents to move from the neighborhood; and (d) some unknown third factor is related to mobility, high blood pressure, and living in a noisy neighborhood.⁶

Noise-Abatement and Noise-Stress Reduction

Do noise-abatement interventions (and their resulting reduction in classroom noise level) decrease or ameliorate the effects of noise in impacted classrooms? Both cross-sectional data collected during the first testing session and longitudinal data looking at changes in the responses of children who moved from noisy to quiet classrooms are relevant to this question. As in the previous section, longitudinal data are based on the attrition (163) sample and, thus, are subject to the attrition bias. The cross-sectional data reported in this section are based on the entire T1 sample (262).

⁶ The explanations that suggest that high blood pressure is the *cause* of the migration from the noisy neighborhoods assume that the child and/or parent perceive that the child is under stress. It is probable that only those children with blood pressures substantially higher than the group mean would fit into this category. Thus, if elevated blood pressure is responsible for increased migration in the noisy neighborhoods, large proportions of those children leaving the noisy neighborhood would have relatively high blood pressures. Analyses of the proportion of children moving from their neighborhoods as a function of whether they attend a noisy or quiet school and whether they have high (80th percentile or above) or low (below the 80th percentile) blood pressure indicate that the proportion of children with high blood pressure who move from the noisy neighborhoods is higher than the proportion of high blood pressure children who move from quiet neighborhoods (Noise \times Blood Pressure interactions: for systolic, $F(1, 246) = 5.42, p < .02$; for diastolic, $F(1, 246) = 5.59, p < .02$). Apparently, a relatively large number of noisy-school children who move do have substantially elevated blood pressure.

Results: Cross-Sectional Analyses

Several of the classrooms in noise-impacted schools had been treated with noise-reducing materials several years before the first testing session. Because they were still relatively noisier than quiet comparison classrooms and because of the presumption that the high noise levels in the homes and play areas of noisy-school children were as important as the actual classroom level, these treated classrooms were not separated from other noisy school classrooms in the previous article (Cohen et al., 1980). To evaluate the effectiveness of this treatment and assess the relative impact of a somewhat quieter classroom on the criterion variables, data from the first testing session were reanalyzed, with classrooms categorized as noisy (97 children), abated (45), and quiet (120). The regression analyses on criterion variables are identical to those described previously except that the noise variable had the three levels described above instead of two (see Table 1, IV).

Noise measures. The mean peak noise level for noisy classrooms was 79.06 dB, for abated classrooms it was 63.17 dB, and for quiet classrooms, 56.60 dB. An analysis of variance indicated a significant difference between these means, $F(2, 34) = 38.45$, $p < .001$. Moreover, preplanned contrast indicated significant differences between noise and quiet, $F(1, 34) = 75.06$, $p < .001$; quiet and abated, $F(1, 34) = 16.93$, $p < .0002$; and noise and abated, $F(1, 34) = 45.89$, $p < .0001$, rooms. In general, it was expected that effects on criterion variables would be directly related to average classroom noise levels and therefore, the mean values would fall in the following order: noise, abated, quiet. Preplanned comparisons reported in this section were employed to directly test this hypothesis.

Child questionnaire. Although noise had a significant impact on children's self-reports of classroom noise, $F(2, 249) = 7.69$, $p < .07$; airplane disturbance in the classroom $F(2, 249) = 7.4$, $p < .0008$; and airplane disturbance at home, $F(2, 249) = 7.78$, $p < .0005$, all reflected a relatively low level of noise annoyance among quiet-classroom children as compared with noisy- and abated-

Figure 3. Systolic and diastolic blood pressure as a function of school noise level and the number of years enrolled in school following T1.

classroom children, whose means on these questions were nearly identical. The multivariate analysis for the child questionnaire data did not indicate any significant effects.

Health. The health cluster analyses indicated Noise \times Months Enrolled in School interactions for both height, $F(2, 237) = 2.83$, $p < .06$, and weight, $F(2, 237) = 4.21$, $p < .01$. These interactions were primarily attributable to relatively low mean heights and weights for those in the abated group who had been enrolled in their schools between 2 and 3½ years. There was also a main effect of noise for the percentage of total school days a child was in attendance, with noisy- and abated-group children attending more often (97.5% for noise and 97.2% for abated) than quiet-group children (94.2%), $F(2, 237) = 11.93$, $p < .0001$. Multivariate analyses for both the noise, $F(6, 470) = 1.58$, $p < .15$, and Noise \times Months, $F(6, 470) = 1.85$, $p < .09$, effects were marginal.

Blood pressure. As is apparent from Table 2, both systolic and diastolic blood pressures appear to vary as a function of noise level, with the highest mean pressure reported for the noise group, followed by a lower blood pressure in the abated group and an even lower pressure in the quiet group. Although the analysis of systolic pressure did not indicate a statistically significant impact of noise, there was a main effect of noise for

Table 2
Mean Blood Pressures (mm Hg) by Classroom Noise Abatement for Cross-Sectional (T1) Data

Blood pressure	Classroom		
	Quiet	Abated	Noisy
Systolic	86.64	88.69	90.09
Diastolic	44.99	46.77	48.46

diastolic pressure, $F(2, 241) = 3.19, p < .04$. The multivariate analysis was not significant.

Preplanned contrasts between the various blood pressure means indicate that for both systolic, $F(1, 235) = 2.61, p < .10$, and diastolic pressure, $F(1, 235) = 5.24, p < .02$, the noise group was different from the quiet group. Comparisons between the quiet group and the abated group indicated marginal differences in both cases—for systolic, $F(1, 235) = 2.21, p < .14$; for diastolic, $F(1, 235) = 3.17, p < .08$. There were no differences between the noise and abated groups for either systolic or diastolic pressure.

Helplessness. The percentage of failure on the second helplessness puzzle was also consistent with the expected order. The noise group was more likely to fail the second helplessness puzzle (57% failed) than either the abated group (47% failed) or the quiet group (35% failed), $F(2, 235) = 4.12, p < .02$. There was no difference between noise groups on the time required to solve the second puzzle. Preplanned contrasts comparing proportions of students solving the second puzzle indicate marginal differences between the quiet and abated groups, $F(1, 235) = 3.10, p < .08$, and the noise and abated groups, $F(1, 235) = 2.70, p < .10$, and a significant difference between noise and quiet, $F(1, 235) = 8.03, p < .005$. These data suggest that noise abatement marginally affected puzzle task performance, with children in abated classrooms performing at a higher level than those in nonabated rooms, but not as well as those in quiet rooms.

Both the noise and the abated group "gave up" on the second puzzle (17% for noise, 16% for abated) more often than the quiet group (3%). The multivariate effect for noise did not, however, reach statistical significance. An analysis including only those children who failed the second puzzle indicated

that the failures of noise- (29%) and abatement-group (35%) children were associated with giving up more often than were the failures of quiet-group children (7% who failed gave up).

School achievement. The achievement tests for reading and math are administered by the school systems during the third but not during the fourth grade. As a result, the scores that were used in the following analyses were recent for third graders (administered at approximately the same time as our own testing) but were 1 year old for fourth graders. Thus, it was expected that noise abatement would affect the achievement scores of third graders who spent a year in their abated classrooms before (and while) taking the test, but not fourth graders, since their classroom assignment at the time that we collected our data was presumably irrelevant to how they performed on a test taken in another classroom 1 year earlier. (Unfortunately, data on the classroom assignment of fourth graders during the year that they were tested were not available.) To test the hypothesis that the achievement scores of third but not fourth graders would be affected by abatement, a Grade \times Noise interaction was added to the noise nested in classrooms analysis of the school achievement cluster. Although there were no effects for the noise or Noise \times Grade interaction on either reading achievement or auditory discrimination, there was a Grade \times Noise interaction for performance on the math achievement test, $F(2, 32) = 3.06, p < .06$; the multivariate for noise was $F(6, 60) = 1.98, p < .08$. As is apparent from Table 3, although grade level did not have a substantial effect on the relative performance of third and fourth graders in quiet schools,

Table 3
Mean (Adjusted) School Achievement Percentiles for Cross-Sectional (T1) Data as a Function of Classroom Noise Abatement and Grade

Classroom	Reading		Math	
	3rd grade	4th grade	3rd grade	4th grade
Noisy	30.30	35.96	34.35	39.35
Abated	47.36	37.90	56.24	37.54
Quiet	37.85	39.09	36.96	42.76

third graders in abated classrooms performed substantially better than those in nonabated classrooms, whereas the reverse was true for fourth graders. It is also apparent from Table 3 that there was a similar pattern for reading test scores, although the Grade \times Noise interaction for reading did not reach statistical significance.

One anomaly of these data is that math (also reading) achievement performance of the third-grade children from abated classrooms in noisy schools is higher than that of third-grade children from quiet schools. It was noted in a previous article (Cohen et al., 1980) that differences between noisy and quiet schools were affected by a number of variables that could not be controlled for in the present study, including school and district teaching policy, teaching quality, level of federal aid to a school, and school administration. It was also suggested that these factors are probably more important than noise in determining school achievement. These problems are reduced substantially when (as in the analysis above) the noise and abated classrooms are in the same district and often in the same school.

Distraction. Analysis of the distraction task data indicated no significant effects.

Results: Longitudinal Analyses

As mentioned earlier, all children from the original sample who were still enrolled in their respective schools were retested 1 year later. The analyses presented below compare those children who were in noisy (non-abated) classrooms during both testings (44 children) with those children who were in noisy rooms during the first testing and abated rooms during the second testing (39 children). Quiet-classroom children were not included in these analyses because of the conceptual problem of evaluating change scores when initial scores are significantly different (see Table 1, V): Only factors for which Noise \times Testing Session and/or Noise \times Months \times Testing Session interactions were significant will be discussed, since at this point we are not concerned with differences between noise/noise and noise/abated groups that occur at both testings (i.e., the main effect for noise) unless an interaction is found.

Noise measures. Before presenting data

Table 4

Mean Classroom Noise Levels for Noisy and Abated-Noise Classrooms at T2

Noise level	Noise measure		
	L_{EQ}	L_{33}	Peak dB (A) ^a
Noisy	70.29	55.82	91.50
Abated	62.82	49.27	71.27

^a Mean peak dB (A) measures at T2 are higher than those recorded at T1. This is because the more sensitive automated equipment used at T2 records peaks that last only a fraction of a second, whereas manual equipment used at T1 required the operator to judge the highest point reached by a fluctuating needle.

on the relationship between the noise-abatement work and the children's performance and health, it is important to determine whether the abatement work was effective. Analyses of the differences in the sound levels in classrooms that were sound attenuated versus those that were not sound attenuated suggests that the abatement work had a significant impact on interior sound levels. As apparent from Table 4, on all three measures— L_{EQ} : $F(1, 20) = 9.39, p < .006$; L_{33} : $F(1, 20) = 4.92, p < .04$; and peak dB: $F(1, 20) = 24.91, p < .0001$ —abated rooms have substantially lower sound levels than non-abated rooms.

Child questionnaire. Children in the noisy group reported more trouble hearing their teacher during the second testing session, whereas those in abated classrooms reported less difficulty—Noise \times Testing Session, $F(1, 48) = 3.98, p < .05$. There were no other Noise \times Testing Session effects on children's questions and no significant multivariate effects.

There were no significant multivariate or univariate interactions of noise and testing session in any of the remaining clusters; thus, no additional data are reported here. It is important to reiterate that school achievement data were available only at T1, and thus, there were no longitudinal school achievement analyses.

Discussion

The cross-sectional comparison of noisy, abated, and quiet classrooms suggests only a minimal impact of the abatement intervention on the criterion variables. Clusters

apparently *unaffected* by abatement (those showing no effects or just noisy- versus quiet-school differences) include children's perceptions of noise and noise interference, health factors, and the auditory distraction measure. On the other hand, two important clusters did provide at least marginal support for an ameliorative effect of abatement. First, abatement did have a marginal effect on whether the child was able to solve the moderately difficult test puzzle in the helplessness task, irrespective of whether the child received a soluble or insoluble first puzzle. It is noteworthy, however, that giving up—the measure designed to provide a direct assessment of feelings of helplessness—was affected only by the noisy-school versus quiet-school distinction. Second, although reading achievement and auditory discrimination ability were unaffected by abatement, there was evidence that math achievement was higher for children in abated than in noisy classrooms. This effect seems especially noteworthy, since it occurs, as predicted, only for those children who took the achievement test at the end of the year that was spent in an abated classroom. It is important to consider, however, that unlike all other measures that were administered in a relatively quiet setting, the achievement tests were actually taken in the classroom. Thus, the relative deficit in math performance of the children from the noisy as opposed to noise-abated classrooms may be attributable to noise interfering with test performance rather than to an aftereffect of noise, which we would expect to occur even outside of the noise-impacted environment.

The *longitudinal* data similarly provide little evidence that children who had been enrolled in a noise-impacted school showed improvement in their performance and/or health following a 1- (school) year experience in a noise-abated classroom. In contrast to the cross-sectional analysis, the longitudinal data did not even indicate improvement in ability to solve the moderately difficult puzzle on the part of children in noise-abated rooms. This failure to mimic the cross-sectional findings may be due to an attrition bias or to the marginality of the effect itself. Unfortunately, school achievement data were not available during the second testing session, and there was no opportunity to reevaluate the ameliorative effects

of noise abatement on school achievement found in the cross-sectional analyses.

It is clear that the ameliorative effects of classroom noise abatement were not substantial, nor did they cover a wide range of measures. There is evidence, however, that abatement affects behavior in the classroom. Children in abated classrooms reported fewer problems hearing their teachers and performed better on school achievement tests than children in nonabated rooms. It is important to reiterate that unlike other measures in the study, school achievement tests were administered in the (noisy or quiet) classroom. It is thus possible that noise-associated deficits on this measure reflect an effect of noise that occurs *during* rather than after exposure.

We can suggest two possible explanations for the general lack of ameliorative effects of classroom noise abatement. First, it is possible that effects of previous noise exposure are relatively long lasting. That is, it takes more than a 1-year reprieve from the noise for a return to more normal levels of behavior and health. Second, since the children are all exposed to the noise outside of the school—in their homes, on the playground, and so forth—a quieter classroom may not have been a sufficient intervention.

In evaluating these results, it is also important to remember that most of the children attending noisy schools spent previous years in nonabated classrooms. Thus, although abatement interventions were not entirely effective for this population, it is possible that children who start to attend school after the entire school has undergone noise abatement (and are thus always in relatively quiet classrooms) would benefit from the interventions.

Conclusions and Implications

The data reported in the analyses of the entire T1 sample (Cohen et al., 1980) indicated effects of aircraft noise on cognitive, motivational, and physiological mechanisms that were consistent with effects found in laboratory settings. The data presented in this article established the stability of these effects over time. Moreover, they reinforce our interpretation of the earlier cross-sectional data that children do *not* adapt to noise over time. The analyses of noise-abate-

ment effectiveness indicate that the abatement is partially effective, with the important school achievement measure showing some improvement for children in noise-abated classrooms.

From a policy point of view, these data support the need for noise-abatement work in these kinds of settings but suggest that noise insulation in the classroom may not be enough. It is likely that more effective noise abatement in classrooms (bringing levels closer to those in quiet schools) and decreased noise exposure *outside of school* would have an increased ameliorative impact. Thus, decreasing overall community noise levels by creating buffer zones between airports and other sources of high-intensity noise and the surrounding communities would be one way of providing more adequate protection for community residents.

The data reported in this and the previous article are part of the Los Angeles Noise Project, an ongoing study that is attempting to provide a sound data base regarding the possible links between community noise exposure and various aspects of behavior and health. The consistency of laboratory and field findings is beginning to increase our confidence in a number of deleterious effects of community noise exposure. This project includes an ongoing attempt to replicate this work, with both a second sample of children living in the air corridor and a sample of children attending schools adjacent to highways. The aim is to increase our understanding of the aftereffects of noise, the possible role of adaptation in mediating such effects, and the impact of noise-abatement intervention on noise-related effects. The strategy of studying effects that are closely linked to laboratory findings together with the use of both cross-sectional and longitudinal approaches in the field helps establish both the scientific validity and practical value of work, with implications for social issues. As these converging approaches eliminate alternative explanations for noise-associated effects, the potential for affecting the formation of public policy increases.

Physiological, Motivational, and Cognitive Effects of Aircraft Noise on Children

Moving From the Laboratory to the Field

ABSTRACT: *A combination of laboratory and field methodologies is suggested as a strategy to increase the influence of psychological research in the formation of public policy. A naturalistic study of the effects of aircraft noise on elementary school children is presented as evidence for the effects of community noise on behavior and as an example of a study that examines the generality of laboratory effects in a naturalistic setting. The study is concerned with the impact of noise on attentional strategies, feelings of personal control, and physiological processes related to health. In general, the results are consistent with laboratory work on physiological response to noise and on uncontrollable noise as a factor in helplessness. Thus children from noisy schools have higher blood pressure than those from matched control (quiet) schools. Noise-school children are also more likely to fail on a cognitive task and are more likely to give up before the time to complete the task has elapsed. The development of attentional strategies predicted from laboratory and previous field research was, on the whole, not found. The implications of the study both for the understanding of the relationship between noise and behavior and for the influencing of public policy are discussed.*

Science's contribution to social policy decisions regarding noise pollution has been primarily limited to the documentation of the impact of high-intensity sound on hearing. Acceptable noise standards used in both national and local statutes are based on research that assesses magnitude of hearing loss at varying intensities and durations of sound. Yet during the last ten years it has become clear that noise can alter nonauditory systems as well as auditory ones. Thus laboratory research has established effects of noise on cognitive, motivational, and general physiological pro-

cesses. For example, noise is associated with alterations in task performance (cf. Broadbent, 1978; Eoeb, 1979), decreased sensitivity to others (e.g., S. Cohen & Lezak, 1977; Mathews & Canon, 1975), and elevation of a number of nonspecific physiological responses (cf. Glass & Singer, 1972; Kryter, 1970). Exposure to noise that is unpredictable and uncontrollable (cannot be escaped or avoided) can also reduce one's perception of control over the environment (e.g., Glass & Singer, 1972; Krantz, Glass, & Snyder, 1974). This loss of control is often accompanied by a depression of mood and a decrease in one's motivation to initiate new responses (Seligman, 1975).

One argument against serious consideration of this evidence when making policy decisions is that it is largely derived from laboratory studies. Since laboratory subjects typically experience a single short period of exposure to high-intensity sound and are aware that their exposure is only temporary, the applicability of these findings to experi-

The research reported in this article was supported by grants from the National Science Foundation (BNS 77-08576 and SOC 75-09224), the National Institute of Environmental Health Sciences (1 RO1 ES0176401 DBR), the Society for the Psychological Study of Social Issues, and the University of Oregon Biomedical Fund.

The authors are indebted to Sheryl Kelly, Laurie Poore, Jerry Lukas, Rich Haller, and Nick Garsbnek; to the administrative staffs of the Los Angeles, Lennox, and Inglewood (California) School Districts; to the staff, teachers, children, and parents of the participating schools; to the California Assessment Program; and to the California Department of Health. ences of chronic noise exposure is questionable. Because of a lack of well-controlled studies of persons routinely living and working under noise, we are unable to say with any certainty if similar effects occur in individuals exposed to noise for prolonged periods.

Our own lack of confidence in the generality of the effects of noise that occurs in laboratory settings translates into a lack of influence in the policy-making process. Legislation restricting noise levels in industrial and community settings usually imposes a heavy economic burden on those responsible for the noise. To convince policymakers that such burdens are justified, there must be substantive evidence that community and/or industrial noise deleteriously affects health and behavior.

Naturalistic studies of the effects of noise that occurs in home, school, or office seem like the obvious alternative to investigations carried out in laboratory settings. However, such studies are correlational. Subjects are not randomly assigned to noisy or quiet settings, and the settings often vary on dimensions other than noise exposure. These problems can be substantially reduced by carefully matching the noise and quiet samples on important dimensions and by statistically controlling for other possible confounds. It is always possible, however, that some unknown factor covaries with exposure to the noise setting and actually causes the effects that the investigator associates with noise. Thus, in isolation, naturalistic studies also provide insufficient evidence for a link between community noise and measures of health and behavior.

It is clear that neither laboratory nor naturalistic studies can in themselves provide what either scientists or politicians would consider convincing evidence for noise-induced effects. What is necessary is an interplay between laboratory and field methodologies. This interplay can take at least two forms. On the one hand, an effect can first be established as reliable within laboratory settings where causal links can be inferred. Then, the robustness of this relationship can be established in a number of naturalistic settings. On the other hand, by first conducting field research, it is possible to isolate important dimensions of a particular problem. At that point, laboratory studies may be useful to rule out plausible alternate explanations often inherent in naturalistic research. Laboratory and field approaches are often pursued to the exclusion of one another, but only by com-

bining these two strategies can we begin to understand the impact of environmental variables in naturalistic settings. Moreover, only when evidence from the laboratory and field converges can a credible scientific case be presented in order to influence public policy.

This emphasis on the interplay between the laboratory and the field is consistent with Campbell and Stanley's (1966) discussion of the inevitable trade-off between well-controlled experimental settings (internal validity) and our ability to generalize across persons and settings (external validity). The laboratory provides the opportunity for an internally valid investigation, but the generality of laboratory findings is severely restricted. Naturalistic studies provide the opportunity to generalize findings to a greater range of persons and settings but often lack the strict control of the laboratory.

The study presented in this article examines the effects of aircraft noise on children. It is particularly concerned with exploring the generality of laboratory work on noise-induced shifts in attentional strategies, feelings of personal control, and nonauditory physiological responses related to health. Our purpose in reporting this study is twofold. First, it is presented as evidence for relationships (or lack of relationships) between aircraft noise exposure and a number of cognitive, motivational, and physiological measures. The article includes short discussions of laboratory and field research in each of the areas of concern. Second, it is presented as an example of an attempt to examine the generality of laboratory effects in a naturalistic setting. In this regard, the study employs an individual testing procedure in a field setting. It uses a matched-group design and attempts to control statistically for a number of possible alternative explanations for correlations between community noise and the various criterion variables.

Overview of the Study

The subjects were children attending the four noisiest elementary schools in the air corridor of Los Angeles International Airport. Peak sound level readings in these schools are as high as 95 dB (A), and the schools are located in an air corridor that has over 300 overflights a day—approximately one flight every 2.5 minutes during school hours (Lane & Meecham, 1974). Three control

schools (quiet schools) were matched with the experimental schools for grade level, for ethnic and racial distribution of children, for percentage of children whose families were receiving assistance under the Aid to Families with Dependent Children program, and for the occupations and education levels of parents. Thus we were able to compare samples of children attending noise schools and quiet schools who were relatively similar in terms of age, social class, and race. A statistical technique described later allowed additional control over these factors.

The study focused on effects occurring outside of noise exposure (i.e., aftereffects). Thus all tasks and questionnaires (except the achievement test records gathered from school files) were administered in a quiet setting—a noise-insulated trailer parked directly outside the school. These data were collected during two 45-minute sessions on consecutive days. Three cognitive tasks were administered during the test periods: One was designed to assess feelings of personal control and the others to determine whether the children employed some common attentional coping strategies. A questionnaire, concerned with responses to noise and two blood pressure measures were also given during the testing sessions. A parent questionnaire dealing with parent response to noise, mother's and father's level of education, and the number of children in the family was sent home with each child. Scores on standardized reading and math tests and data on absenteeism were collected from school files.

The study included children from all noise-impacted third- and fourth-grade classrooms in each noise school as well as children from an equal number of classrooms in quiet schools. To ensure that performance differences between children from noise schools and those from quiet schools could not be attributed to noise-induced losses in hearing sensitivity, an audiometric pure-tone threshold screening was administered to each child. Children were screened at 25 dB for select speech frequencies (500, 1000, 2000, and 4000 Hz). Children failing to detect 25 dB tones at any one of these frequencies in either ear were not included in the study. Six percent of the noise-school children and 7 percent of the quiet-school children failed the screening. A total of 262 subjects (142 from noise schools and 120 from quiet schools) remained in the study. Individual analyses, how-

ever, sometimes contain fewer subjects because of missing data.

Data compiled from the parent questionnaire allowed us to determine the degree of similarity of the prematched noise and quiet samples. Analyses of variance indicated that there were no differences between the samples on the various social class factors. The mean number of children per family was 3.54 in the noise sample and 3.88 in the quiet sample. Levels of parent education were also equivalent, falling between some high school (scaled as 3) and high school graduate (scaled as 4). The mean level of education for fathers was 3.75 for noise-school children and 3.41 for quiet-school children, and for mothers, 3.64 and 3.35, respectively. The racial distributions, however, differed significantly, $\chi^2(3) = 10.5$, $p < .01$, with the noise group containing more blacks (32% vs. 18%) and the quiet group more Chicanos (50% vs. 33%). Noise and quiet samples had nearly equal percentages of whites (32% and 29%, respectively) and of unidentifiable or mixed-race children (3% in each sample).

The two samples also differed on mobility, with children in the quiet sample having lived in their homes longer (a mean of 49.6 months vs. 41.4 months) and attended their schools for longer periods (a mean of 43.2 months vs. 36.0 months) than noise children, $F(1, 270) = 4.8$, $p < .03$, and $F(1, 270) = 12.9$, $p < .001$, respectively. Length of school enrollment was not related to father's education, mother's education, or the number of children in the family. Moreover, the noise and quiet samples were relatively equal on these various social class factors across all durations of exposure. This finding suggests that the decision to continue living in the noise-impacted area was not determined by the parents' socioeconomic status. There were, however, more blacks and whites in the noise group with less than 2 years' exposure than there were in the equivalent quiet group, $\chi^2(4) = 12.04$, $p < .02$. There were no differences in racial distribution for other exposure durations.

Statistical Controls

A regression technique was used to compensate for differences between the noise and quiet samples on racial distribution and mobility (J. Cohen, 1968). In general, the regression analysis allows one to determine the relation between two variables while

ing evidence for noise-induced physical disease (cf. S. Cohen, Glass, & Phillips, 1979; Kryter, 1970). It is well-established, however, that short-term exposure to relatively high sound levels in laboratory settings can alter physiological processes. Physiological changes produced by noise consist of non-specific responses typically associated with stress reactions, including increases in electrodermal activity, catecholamine secretions, vasoconstriction of peripheral blood vessels, and diastolic and systolic blood pressure. Because such changes, if extreme, are often considered potentially hazardous to health, many feel that pathogenic effects of prolonged noise exposure are likely. Laboratory evidence that some components of the physiological response to noise do not habituate (Jansen, 1969) lends fuel to this argument, but is difficult to interpret in light of evidence from other laboratories indicating complete habituation (Glass & Singer, 1972).

A number of studies of workers in noisy industries have indicated health problems for those exposed to intense noise levels. Included are respiratory problems, such as sore throat, and allergic, musculoskeletal, circulatory, neurological, cardiovascular, and digestive disorders (e.g., Anticaglia & Cohen, 1974; A. Cohen, 1973). However, all of the industrial noise studies are subject to serious criticism because of their failure to control for other adverse workplace or job factors, for example, task demands and risks, that often covary with the noisiness of the job (cf. S. Cohen et al., 1979; Kryter, 1970). It is also important to note that several industrial surveys have failed to find a relation between noise and ill health (e.g., Finkle & Poppen, 1948; Glorig, 1971).

There are no existing controlled studies on the impact of noise on nonauditory health in children (Mills, 1975). Recent theoretical work, however, argues that children (along with the old, individuals in institutions, and persons suffering from other sources of stress) may be particularly susceptible to noise-induced illness because they lack the ability to temporarily escape their noisy environments (S. Cohen et al., 1979). It is suggested that this inability to escape at will can cause both an increase in overall duration of noise exposure and an increase in feelings of helplessness. This effect is important, since feelings of helplessness have been implicated as possible causal factors in illness (Seligman, 1975).

Each child's resting blood pressure (systolic and diastolic) was taken on an SR-2 Physiometrics automated blood pressure recorder.³ To accustom the children to the blood pressure measurement technique, an initial measurement was made at the beginning of the first day of testing. A short explanation of the technique and the concept of blood pressure was given at this time, and questions were solicited and answered. This initial measurement was not recorded. Each child's blood pressure was measured again on the first day and once more on the second day. The blood pressure data are based on the mean systolic and diastolic pressures for these two measurements. The graphic output of the machine was coded after the study was completed, with coders blind to experimental condition. Each child's height and weight were also measured. Absenteeism was used as an indirect measure of health, since absence from school is often attributable to illness. These data were available from school files.

Health measures were separated into two multivariate clusters: general health measures and blood pressure. This procedure was necessary because two of the general health measures—height and ponderosity (weight/height²)—were required as controls for the blood pressure analyses (cf. Voors et al., 1976). (The ponderosity index was chosen as a measure of obesity because of its high correlation with body fat.) The multivariate F for the effects of noise on the general health cluster was significant, $F(3, 235) = 8.04, p < .001$. Although noise-school children were shorter and weighed less than quiet-school children, neither of these differences reached significance, $F(1, 237) = 1.77, p < .18$, and $F(1, 237) = 1.07, p < .30$, respectively. Surprisingly, noise-school children attended school a higher percentage of the time (97.5% vs. 94.2%) than their quiet-school counterparts did, $F(1, 237) = 21.80, p < .001$.

The multivariate F for the effects of noise on systolic and diastolic blood pressure was significant, $F(2, 244) = 2.98, p < .05$. As is apparent from Figure 1, children from noise schools had higher blood pressure than their quiet-school counterparts did, with $F(1, 245) = 4.61, p < .03$, for

³ This instrument is an electronic infrasonic device that records on a rotating paper disc. Measurements were taken with a rubber cuff entirely encircling the upper arm. The reliability of this device for blood pressure measurement in children has been established in previous work (e.g., Voors, Foster, Frerichs, Weber, & Berenson, 1976).

controlling (covarying or partialing out) for one or more other variables. For example, one can look at the relation between noise level and blood pressure after functionally equating the noise and quiet groups on mobility and race. All data analyses reported in this article include controls for the number of children in the child's family, the grade in school, the number of months enrolled in school (years in residence for the parent questionnaire), and race.¹ These control factors were forced into the regression first, followed by noise and then the Noise \times Months Enrolled in School interaction. The interaction indicates whether length of exposure affected the various criterion measures. Additional controls were used in the analyses of blood pressure, school achievement, and selective inattention. The use of these controls is described in appropriate sections. This conservative analysis looks at the effects of noise and the interaction between noise and length of enrollment after functionally equating the noise and quiet groups on grade, race, social class, and mobility, as well as on any additional control factors employed in a particular analysis.

The various measures were analyzed in predetermined multivariate clusters created on the basis of theoretical consideration.² This form of analysis helps to decrease the high probability of chance findings that occur when a large number of analyses are necessary (cf. Bock, 1975).

Noise Measures

Interior sound levels (without children) were measured inside each classroom with Tracoustics (SLM S2A) sound level meters. Sound levels were monitored for a 1-hour period in the morning and a 1-hour period in the afternoon. Peak sound levels in terms of dB (A) were recorded for both morning and afternoon sessions. The overall mean peak for classrooms in noise schools was 74 dB and in quiet schools 56 dB. The highest reading in a noise-school classroom was 95 dB, while the highest reading in a quiet school was 68 dB.

The questionnaire administered to each child assessed his or her perception of classroom and home noise levels. The parent questionnaire also included questions on perception of home noise level as well as queries on how long the child had been enrolled in the present school and how long he or she had lived at their present address. Data on school enrollment were also available from school files. Noise contours (compiled by the Los

Angeles International Airport) provided approximations of the sound levels outside the homes of noise-school children.

The multivariate F for the effects of noise on the children's noise questionnaire was significant, $F(9, 246) = 3.10, p < .002$, thus allowing interpretation of the univariate regressions. Children in noise schools reported that their classrooms were noisier, $F(1, 254) = 5.49, p < .02$, and that airplanes bothered them more in the classroom, $F(1, 254) = 14.74, p < .001$, than children in quiet schools did. They did not, however, report having more trouble hearing their teacher.

In regard to home noise, children from air-corridor schools were more bothered by airplane noise than their quiet-school counterparts were, $F(1, 254) = 15.75, p < .001$. However, noise- and quiet-school children did not differ in ratings of home noise. Neither the multivariate F nor any univariate regression indicated any significant effects for the Noise \times Months in School interaction on the children's questionnaire.

The multivariate F for the effects of noise on the parents' noise questionnaire was also significant, $F(2, 221) = 124.2, p < .001$. Parents of children from the air-corridor schools indicated both that there were higher levels of noise in the home, $F(1, 232) = 37.33, p < .001$, and that they were bothered more by noise, $F(1, 232) = 240.07, p < .001$, than the parents of children attending quiet schools indicated. The home noise level reported by the parents of noise-school children increased with the number of years they had lived in their present residence, $F(1, 220) = 3.11, p < .08$. This effect must be interpreted carefully, however, since both the univariate and multivariate F s were only marginally significant.

Effects of Noise

PHYSIOLOGICAL RESPONSE AND HEALTH

Aside from temporary and permanent effects on hearing, previous research provides little convinc-

¹ Parent education was excluded as a control because data on this factor were not available for a number of children. As mentioned earlier, the noise and quiet samples were closely matched on education. Race was dummy-variable coded (see Overall & Klett, 1972).

² There were separate clusters for general health, blood pressure, helplessness, child questionnaire, and parent questionnaire. The selective inattention analyses were run as univariates, since each analysis required a unique control factor.

systolic pressure and $F(1, 245) = 4.86, p < .03$, for diastolic pressure.⁴ Unadjusted means for systolic pressure were 89.68 mm for the noise group and 86.77 mm for the quiet group. Diastolic means were 47.84 mm for the noise group and 45.16 mm for the quiet group. A marginal interaction, $F(1, 244) = 3.30, p < .07$, between noise and months in school suggests that systolic pressure differences between noise and quiet groups are greatest during the first few years of school enrollment; differences after this point remain constant. Figure 1 reflects a similar pattern for diastolic pressure. This interaction does not, however, reach even marginal statistical significance.⁵

HELPLESSNESS

Both laboratory and community noise research suggests the possibility that high-intensity noise exposure induces feelings of helplessness. According to Seligman (1975), a psychological state of helplessness frequently results when we continually encounter events (especially aversive ones) that we can do nothing about. The state of helplessness includes a perception of lessened control over

one's outcomes, a depression of mood, and a decrease in one's motivation to initiate new responses. Extreme effects of helplessness include fear, anxiety, depression, disease, and even death.

A number of researchers have induced helplessness effects in the laboratory by exposing subjects to uncontrollable bursts of noise (Hiroto, 1974; Krantz et al., 1974). Moreover, survey data reporting high levels of annoyance but low levels of complaints from noise-impacted populations have similarly been interpreted as reflecting a helplessnesslike state (Herridge, 1974). This finding, however, is subject to a number of alternative explanations, and thus the helplessness interpretation is only suggestive.

Performance on a cognitive task preceded by a success or failure experience was used in the present study to examine the effect of noise on response to failure and on persistence on a difficult task. Response to failure is a standard measure of susceptibility to helplessness. Thus, if noise-school children were more susceptible to helplessness, they would show greater effects of a failure experience than their quiet-school counterparts would. A lack of persistence (or a "giving-up" syndrome) is considered a direct manifestation of the helpless state.

Each child was given a treatment puzzle to assemble after the tester demonstrated the task with another puzzle. All puzzles were based on the same nine pieces and required the child to fill in a template of a familiar shape. One half of the

Figure 1. Systolic and diastolic blood pressure as a function of school noise level and duration of exposure. (Each period on the years-exposure coordinate on the figure represents approximately one quarter of the sample. For example, 25% of the sample had been enrolled in the present school less than 2 years.)

⁴ Both the noise-school and quiet-school children have lower mean blood pressures than children of similar ages tested in recent studies (e.g., Voors et al., 1976). It is important to note, however, that it is difficult to compare absolute blood pressure levels across studies, since blood pressure is strongly influenced by environmental and genetic characteristics of the population being studied, the conditions under which measurement occurs, and the measurement device.

⁵ To investigate whether elevations in blood pressure occurred equally across races, separate regressions were calculated for whites, blacks, and Chicanos. Since the number of subjects in each of these regressions is small, only very substantial mean differences will reach statistically significant levels. Blacks and Chicanos attending noise schools had higher systolic ($p < .05$ for blacks, $p < .25$ for Chicanos) and diastolic ($p < .25$ for blacks, $p < .10$ for Chicanos) pressure than their quiet-school counterparts did. For whites, there were no main effects of noise, but an interaction between noise and length of school enrollment indicated that an initial inflation of pressure for noise-school children disappeared as length of enrollment increased ($p < .01$ for both systolic and diastolic). These race differences will be pursued in a later paper.

children received an insoluble (failure) puzzle, and one half received a soluble (success) puzzle. The soluble puzzle was a circle, and the insoluble puzzle was a triangle. Each child was allowed to work on the treatment puzzle for 2.5 minutes. After time was up on the first puzzle, the child was given a second, moderately difficult puzzle to solve. The second (test) puzzle was the same—a square—for all (success and failure) children. The child was allowed 4 minutes to solve the second puzzle. Whether or not the puzzle was solved, time to solution and the child's persisting or giving up before the 4 minutes had elapsed were used as measures of helplessness. We expected that children from noisy schools would be more susceptible to a failure (helplessness) manipulation than children from quiet schools would be, and thus would be less likely to solve the puzzle, slower to find the solution, and more likely to give up on the second puzzle following an insoluble (failure) treatment. Moreover, children from noisy schools, irrespective of their success-failure condition, were expected to give up more often than quiet-school children.

A large proportion (34%) of the children assigned to the success condition, and thus receiving a soluble treatment puzzle, failed to solve the treatment puzzle within the 2.5 minutes allowed. Since the puzzles were considered quite simple and had been pilot tested on children of the same age group, this result was quite unexpected. Although the fact that a number of children self-selected themselves into a failure condition makes interpretation of success-failure effects impossible, comparisons between the children from noise schools and those from quiet schools, irrespective of (controlling for) their pretreatment, are still valid.

Except for the first analysis, which includes only those children who worked on soluble treatment puzzles (success condition), the following analyses also include factors for success-failure (those who solved and those who did not solve the success treatment puzzle are treated as separate groups) and the interaction between success-failure and noise. The control factors were forced into the regression first, followed by success-failure (dummy coded), noise, and the Noise \times Success and Noise \times Months/Enrolled interactions. Because of the difficulty in interpreting success-failure effects, they are not discussed. Moreover, since there were no significant interactions between

Figure 2. Performance on the second (test) puzzle as a function of school noise level and duration of exposure. (Each period on the years-exposure coordinate on the figure represents approximately one quarter of the sample. For example, 25% of the sample had been enrolled in the present school less than 2 years.)

success-failure and school noise level, the reported results are limited to the overall effects of noise.

First, an examination of only those who were assigned to the success treatment condition indicates that children from noise schools were more likely to fail to solve the treatment puzzle (41% failed) than children from quiet schools were (23% failed). This effect, however, was only marginally significant, $F(1, 131) = 3.62, p < .07$. Second, there were similar effects of noise on the second puzzle, which occurred irrespective of whether the child received a success (solved or not) or failure treatment. As was the case with the first puzzle, noise-school children were more likely to fail the second puzzle (53% failed) than quiet-school children were (36% failed), $F(1, 246) = 5.99, p < .09$, and were more likely to give up, $F(1, 246) = 11.15, p < .001$, than their quiet-school counterparts were, multivariate $F(3, 244) = 4.59, p < .004$. As is apparent from Figure 2, a marginal interaction between noise and months enrolled in school, $F(1, 243) = 3.27, p < .07$, suggests that the longer a child had attended a noise school, the slower he or she was in solving the puzzle. However, the multivariate F for this interaction was not significant.

Although the preceding analyses indicate that children from noise schools are generally less capable of performing a cognitive task (at least puzzle solving) than children from quiet schools are, they provide only suggestive evidence that noise-school children feel or act as if they have less control over their outcomes. The strongest hint that failure on these puzzles on the part of noise-school children is related to helplessness is found in the data indicating that noise-school children were more likely to give up before their allotted time had elapsed than their quiet counterparts were. It is possible, however, that a constant proportion of children who failed on the second puzzle gave up. It would follow that the amount of giving up in the noise condition was inflated by the fact that there was a greater pool of failures. This interpretation suggests that increased giving up under the noise condition cannot necessarily be viewed as a sign of helplessness. A final analysis addresses this point. This analysis, which includes only those children who failed the second puzzle, indicates that the failures of noise-school children were associated with giving up (31% of those who failed gave up) more often than the failures of quiet-school children were (7% of those who failed gave up), $F(1, 103) = 5.85, p < .025$. Thus, even though all of these children failed to solve the puzzle, noise-school children were less likely to persist than their quiet-school counterparts were.

ATTENTIONAL PROCESSES DURING NOISE

Human performance studies report that noise often results in a restriction (or focusing) in one's breadth of attention (Broadbent, 1971; Hockey, 1970). Cues irrelevant to task performance are dropped out first, and then, if attention is further restricted, relevant task cues are eliminated. Performance improves under noise when discarded cues are those that are distracting or competing with primary task cues. Performance is adversely affected, however, when a task requires a wide breadth of attention and when focusing results in the neglect of relevant as well as irrelevant cues. Similarly, focusing can have a negative impact on interpersonal behavior when subtle social cues (e.g., another's look of distress) are dropped out, but can improve the quality of an interaction when the discarded cues are merely distracting (S. Cohen & Lezak, 1977).

There is suggestive evidence that an attentional focusing strategy will persist even after noise is terminated. A number of studies have shown noise effects on performance and interpersonal behavior (e.g., Donnerstein & Wilson, 1976; Glass & Singer, 1972). These aftereffects of noise are consistent with what one would expect to occur when one uses a focusing strategy (S. Cohen, 1978). As yet, however, there is no direct evidence that attentional focusing occurs following exposure to noise in either the laboratory or the field.^a

Selective inattention. A strategy that is similar (and possibly identical) to attentional focusing has been proposed by Deutsch (1964) to account for the effect of community noise on the verbal abilities of children. Deutsch suggests that children reared in noisy environments become inattentive to acoustic cues. That is, they tune out their acoustic environment. (This could be viewed as their focusing their attention on other aspects of their environment.) Children who tune out their noisy environments are not likely to distinguish between speech-relevant and speech-irrelevant sounds. Thus, they lack experience with appropriate speech cues and generally show an inability to recognize relevant sounds and their referents. The inability to discriminate sound is presumed to account, in part, for subsequent problems in learning to read. Although recent research suggests that children living and attending school in noisy neighborhoods are poorer at making auditory discriminations and in reading (Bronzaft & McCarthy, 1975; S. Cohen, Glass, & Singer, 1973), there is no direct evidence for the selective inattention mechanism. An alternative explanation is that noise masks parent and teacher speech, similarly resulting in a lack of experience with appropriate speech cues and, as a consequence, in reading deficits.

The present study attempts to assess the relation between environmental noise level and the selective inattention strategy in order (a) to determine the generality of noise-induced shifts in attention that occur in laboratory settings and (b) to test Deutsch's (1964) hypothesis. In line with

^a The only study on the impact of chronic noise exposure on attentional focusing resulted in rather ambiguous findings, with children from noisy homes (as reported by parents) exhibiting general performance deficits but no focusing strategy (Heft, 1979). A replication of the incidental memory task used in the Heft study was administered in the present study. Errors in administering the task, however, made the data uninterpretable.

the testing of the Deutsch hypothesis, the relation of the above-mentioned variables to auditory discrimination and reading achievement is also assessed.

Because children who are relatively inattentive to acoustic cues should be less affected by an auditory distractor, distractibility was used as a measure of selective inattention. Under both ambient and distracting conditions, the subjects performed a task consisting of crossing out the e's in a two-page passage from a sixth-grade reader. They were instructed to move from left to right and from top to bottom of the page, as if they were reading, and to go as fast as they could without missing any e's. Each subject worked on a short practice paragraph and then on the task for 2 minutes. Two versions (different samples of prose) were used.

In the distraction condition, the child worked on one of the versions of the task while a tape recording of a male voice read a story at a moderate volume. In the no-distraction condition, the alternative form of the task was completed under ambient sound conditions. The distraction and no-distraction tasks were administered on different testing days. Both the order of alternative versions of the task and the experimental conditions were counterbalanced. The criterion measure was performance (percentage of e's found) on the distraction task after the scores were adjusted for no-distraction performance. It was expected that the children from noise schools would be less affected by distraction than the children from quiet schools. Since selective inattention is a strategy that develops over time, it was also predicted that this tuning-out strategy would increase with increased exposure (S. Cohen et al., 1973).

Separate analyses examined the number of lines completed under distraction and the percentage of e's in the completed lines that were found under distraction. No-distraction performance (number of lines in the first analysis and percentage of e's in the second) was added as an additional control variable in order to equate the children on their ability to perform the task under quiet conditions. There were no differences between the noise group and the quiet group (nor was there an interaction) on the number of lines completed under distraction. There was, however, a significant interaction between noise-quiet and months enrolled in school, $F(1, 237) = 5.05, p < .03$, for the percentage-of-e's-found measure. As is apparent from Figure 3,

Figure 3. Distractibility as a function of school noise level and duration of exposure. (Each period on the years-exposure coordinate on the figure represents approximately one quarter of the sample. For example, 25% of the sample had been enrolled in the present school less than 2 years.)

the children in noise schools did better than the quiet group on the distraction task during the first 2 years of exposure and did worse after 4 years of exposure. Contrary to earlier evidence, this finding suggests that as the length of noise exposure increases, children are more, rather than less, disturbed by auditory distractors. One possible explanation for this effect is that at first, the children attempt (somewhat successfully) to cope with noise by tuning it out. Later, however, as they find that the strategy is not adequate, they give up. This interpretation is consistent with the helplessness data.

As suggested earlier, reading deficits in children from noisy neighborhoods have been attributed to noise-impacted children's selective filtering out of acoustic cues. Auditory discrimination and reading achievement were assessed in an attempt to replicate previous work and to determine whether there was an association between these measures and the children's attentional strategies. Standardized reading and math tests (administered during the second and third grades by the school system) were gathered from school files, and the Wepman Auditory Discrimination Test (Wepman, Note 1) was administered individually to children in the soundproof van. The Wepman test consists of 40 pairs of words, some of which differ from each other in either initial or final sound, for example,

sick-thick or *map-nap*. The pairs of words are recorded on tape and presented to each child through earphones. The child is instructed to report if the two words in each pair are the same or different. Control word pairs, in which the words are the same, allow for the elimination of children who have problems with same-different judgments or who are not attending to the task.

In order to roughly equate the noise and quiet conditions on the aptitude of the children at the time they entered school, the analyses of school achievement and auditory discrimination scores included an additional control for the mean cognitive abilities of the child's class on entering the first grade. None of the multivariate or univariate analyses were significant for this cluster. Math, reading, and auditory discrimination were all unrelated to both noise and the Noise \times Months Enrolled in School interaction.

Further analyses (Pearson correlations) suggest that the children who were better at auditory discriminations were also better on both the reading test, $r(231) = .19$, $p < .05$, and the math test, $r(231) = .18$, $p < .05$. There were, however, no significant relations between these variables and the selective inattention measure. The same analyses, including only noise-school children, and correlations partialing out control variables for both the entire sample and the noise sample yielded similar results. In summary, there is no evidence that aircraft noise affects reading and math skills, or that these skills are related to a selective inattention strategy.

Classroom as the unit of analysis. Since noise would be likely to have an impact on school achievement by affecting behavior in the classroom, a second analysis of the school achievement cluster was performed with classroom, rather than individual child, as the unit of analysis. This covariance analysis treated the control factors as covariates and months enrolled in school, noise, and classrooms (nested in noise) as independent variables. This analysis is considerably more conservative than the previous analysis because the degrees of freedom in the denominator are based on the number of classrooms (37) rather than on the number of children (262). The results for the school achievement cluster were the same.

The classroom analysis was not used for the other clusters, since those measures were not achievement oriented and thus were presumed not to be classroom mediated. The subjects were also

tested individually, not in the classroom. Even using this ultraconservative technique, however, a reanalysis of the other clusters indicates very similar results for the parent-questionnaire, blood pressure, and helplessness clusters. Differences between the noise group and the quiet group on the child-questionnaire and selective inattention clusters, which were significant in the previous analysis, did not reach statistical significance with classroom used as the unit of analysis.

QUIET HOMES AND NOISY SCHOOLS

To determine whether or not living in a relatively quiet home (at least in terms of aircraft noise) would lessen the impact of school noise, we isolated the children living in the 20 quietest homes in the noise sample, that is, in homes with contour levels of less than 68 in terms of the Community Noise Equivalency Level (CNEL).⁷ These children were then compared (using the regression techniques described earlier) with the remainder of the noise sample and with the entire quiet sample.⁸ In no case was there a difference between these quiet-home children and the remaining children of the noise sample. In a number of cases, however, even this small group of 20 showed the effects of noise reported earlier. Thus the noise-sample children from quiet homes were less likely to solve the first helplessness task puzzles than the quiet-sample controls were, $F(1, 132) = 3.04$, $p < .10$. The longer a child had attended a noisy school, the less likely he or she was to solve either the first puzzle, $F(1, 130) = 4.06$, $p < .05$, or the second puzzle, $F(1, 240) = 2.07$, $p < .15$. Moreover, children from quiet homes but noisy schools were more likely to fail, $F(1, 244) = 6.20$, $p < .01$, and to give up, $F(1, 244) = 11.95$, $p < .001$, on the second puzzle than children from quiet schools were, multivariate $F(3, 244) = 4.71$, $p < .003$. Further, their failures on the second puzzle were associated with giving up more often than the failures of quiet-school children were, $F(1, 102) = 6.27$,

⁷ CNEL is a measure of community noise giving more weight to noise occurring between 1900 and 2200 hours and the most weight to noise occurring between 2200 and 0700 hours (cf. Peterson & Gross, 1972).

⁸ Noise was dummy coded. The two contrasts discussed in this section were used to determine the impact of noise. This is a conservative technique of doing the contrasts, since the error term for the entire sample is used in calculating the F .

.025. Noise-school children from quiet homes also had both higher systolic blood pressure, $F(1, 240) = 3.59, p < .06$, and higher diastolic blood pressure, $F(1, 240) = 5.32, p < .02$, than children from quieter schools did, multivariate $F(2, 239) = 2.84, p < .06$. There were no effects, however, on the selective inattention task (crossing out e's under distraction condition), as reported for the entire sample.

These analyses suggest that living in a relatively quiet neighborhood did not lessen the cumulative impact of exposure to noise at school. The reason may be that the noise experienced during school attendance is sufficient to create noise effects.

Air Pollution

A possible alternative explanation for differences between the noise and quiet samples is air pollution levels. Such an alternative is very unlikely. Sulfur dioxide was minimal at all the school sites, never exceeding the California standard (South Coast Air Quality Management District, Note 2; State of California, Note 3). Ozone and nitrogen dioxide standards were exceeded, but maximum levels were slightly higher at the control schools than at the airport schools. The maximum 1-hour rates in any school area for ozone (.21 parts per million) and NO_2 (.60 ppm) were below levels that generally show any effects on human behavior or health (Morrow, 1975; National Academy of Sciences, Note 4). Maximum carbon monoxide was slightly higher in the airport schools (30 vs. 27, 22 ppm), but average values were identical (6 ppm). The differences in maximum values of 8 ppm are negligible, and human effects from CO concentrations of less than 40 ppm are extremely rare (National Air Pollution Control Administration, 1970). Note that we have used maximum values in arguing against an air pollution alternative, thus presenting a very conservative counter-argument. Average values in all cases were considerably below established standards.

Conclusions

In general, the evidence presented in this article is consistent with laboratory work on physiological response to noise and on uncontrollable noise as a factor in helplessness. Thus children from noisy schools have higher blood pressure and are more likely to give up on a task than children from

quiet schools are. The development of attentional strategies predicted from laboratory work and previous field research was, on the whole, not found. Contrary to prediction, increased years of exposure led to children's being more distractible rather than less. However, a general deficit in task performance on the puzzle task and increased distractibility do seem to support the more general hypothesis that prolonged noise exposure affects cognitive processes.

These data are most interesting, however, because of the tentative answers they provide concerning questions of adaptation to noise over time. One interpretation of the data is that they indicate some habituation of physiological stress response but show no signs of adaptation of cognitive and motivational effects. In fact, in a number of cases, increased length of exposure resulted in an increased negative impact of noise. First, the only evidence for an adaptation effect is provided by the systolic blood pressure data. On that measure, the greatest difference between the noise and quiet groups occurred during the first 2 years of exposure. As length of exposure increased, these differences leveled out but still remained substantial. Perceptions of noise and noise annoyance did not adapt. Thus children from noise schools and their parents reported more noise and being more bothered by noise. Parents, in fact, reported higher levels of noise as their length of residence in the noisy area increased. Neither the cognitive deficits on the helplessness puzzles (which actually increased over time) nor the giving-up syndrome of the children from noise schools lessened with increased length of exposure. Finally, although noise-school children were initially less affected by an auditory distractor, increased length of exposure (beyond 4 years) seemed to result in greater distractibility. Thus the preponderance of evidence suggests a lack of successful adaptation over time. The above interpretation, however, is only tentative. Although length-of-exposure differences may be due to increased exposure to noise, they may also be attributable to some unknown factors that differentiate between children who continue to live in the air corridor and those who move, or to some combination of exposure and these factors.

It should be noted that the failure of the present study to replicate the previously reported relation between community noise and reading ability (Bronzaft & McCarthy, 1975; S. Cohen et al.,

1973) may be attributable to an experimental design insensitive to noise-induced differences in school achievement. In both of the earlier studies, all the students attended the same school. Moreover, in the Cohen et al. study, students from both noisy and quiet apartments were taught in the same classrooms by the same teachers. In the present study, noise-sample children and quiet-sample children attended different schools, were in different classrooms, and had different teachers. It is likely that these factors add substantial error variance to the equation, making the detection of a small effect of noise quite difficult.

Can we conclude that community noise has effects that are similar to noise-induced effects reported in the laboratory literature? The similarity of our results to those reported in laboratory settings is striking. However, we still must be cautious. Replications of these results in other settings and with other populations are required before definitive conclusions are possible. To this end, our own research program includes an ongoing replication of this study, with a population exposed to traffic noise, as well as plans to collect longitudinal data on the children attending airport schools.

What conclusions can we make in regard to public policy? From a policy point of view, these data are valuable but not sufficient. At least 8 million people in this country are exposed to aircraft noise (U.S. Environmental Protection Agency, 1974), and the vast majority of noise-impacted communities have racial and social class compositions more similar to the composition of the present sample than to that of the general population (U.S. Environmental Protection Agency, Note 5). In combination with the laboratory noise literature, these data clearly suggest lending additional weight to the possible impact of aircraft noise on psychological adjustment and on nonauditory aspects of health. Replications of these results, however, would substantially increase their potential influence in the realms of both science and social policy.

APF National Media Awards for 1980

The American Psychological Foundation annually presents National Media Awards to individuals in order to recognize and encourage outstanding, accurate coverage which increases the public's knowledge and understanding of psychology. Awards are made in five categories: (1) television/film; (2) radio; (3) newspaper reporting; (4) magazine writing; and (5) books/monographs. This year the winner in each category will receive \$1,000, a citation, and an invitation to attend the APA Annual Convention in Montreal, September 1-5, 1980. The Foundation will pay travel expenses for each winner for three days.

Materials must include references to psychology and/or psychologists and depict the activities, ideas, and findings of individual psychologists or applications of psychological sciences. For example, entries that focus on social issues and mental health must include specific references to psychology and/or psychologists to be eligible. Materials nominated must have been produced or published on or after May 1, 1979, and before May 1, 1980. Nominations may be made by anyone, including the author, producer, etc. Deadline for receipt of entries is May 10, 1980. For entry forms write to Public Information Office, American Psychological Association, 1200 Seventeenth Street, N.W., Washington, D.C. 20036.

The American National Standards Institute, Inc. (ANSI) is the national coordinator of voluntary standards development and the clearinghouse in the U.S. for information on national and international standards.

The Acoustical Society of America (ASA) is an organization of scientists and engineers formed in 1929 to increase and diffuse the knowledge of acoustics and to promote its practical applications.

ANSI S12.60-2002

AMERICAN NATIONAL STANDARD
**Acoustical Performance Criteria,
Design Requirements,
and Guidelines for Schools**

Secretariat
Acoustical Society of America

Approved 26 June 2002
American National Standards Institute, Inc.

Abstract

This Standard provides acoustical performance criteria, design requirements, and design guidelines for new school classrooms and other learning spaces. The standard may be applied when practicable to the major renovation of existing classrooms. These criteria, requirements, and guidelines are keyed to the acoustical qualities needed to achieve a high degree of speech intelligibility in learning spaces. Design guidelines in informative annexes are intended to aid in conforming to the performance and design requirements, but do not guarantee conformance. Test procedures are provided in an annex when conformance to this standard is to be verified.

AMERICAN NATIONAL STANDARDS ON ACOUSTICS

The Acoustical Society of America (ASA) provides the Secretariat for Accredited Standards Committees S1 on Acoustics, S2 on Mechanical Vibration and Shock, S3 on Bioacoustics, and S12 on Noise. These committees have wide representation from the technical community (manufacturers, consumers, trade associations, general-interest and government representatives). The standards are published by the Acoustical Society of America through the American Institute of Physics as American National Standards after approval by their respective Standards Committees and the American National Standards Institute.

These standards are developed and published as a public service to provide standards useful to the public, industry, and consumers, and to Federal, State, and local governments.

Each of the accredited Standards Committees, operating in accordance with procedures approved by American National Standards Institute (ANSI), is responsible for developing, voting upon, and maintaining or revising its own Standards. The ASA Standards Secretariat administers Committee organization and activity and provides liaison between the Accredited Standards Committees and ANSI. After the Standards have been produced and adopted by the Accredited Standards Committees, and approved as American National Standards by ANSI, the ASA Standards Secretariat arranges for their publication and distribution.

An American National Standard implies a consensus of those substantially concerned with its scope and provisions. Consensus is established when, in the judgment of the ANSI Board of Standards Review, substantial agreement has been reached by directly and materially affected interests. Substantial agreement means much more than a simple majority, but not necessarily unanimity. Consensus requires that all views and objections be considered and that a concerted effort be made towards their resolution.

The use of American National Standards is completely voluntary. Their existence does not in any respect preclude anyone, whether he or she has approved the Standards or not, from manufacturing, marketing, purchasing, or using products, processes, or procedures not conforming to the Standards.

NOTICE: This American National Standard may be revised or withdrawn at any time. The procedures of the American National Standards Institute require that action be taken periodically to reaffirm, revise, or withdraw this Standard.

Foreword

[This foreword is for information only and is not an integral part of American National Standard *Acoustical Performance Criteria, Design Requirements, and Guidelines for Schools*.]

This standard contains 7 annexes.

This standard was developed under the jurisdiction of Accredited Standards Committee S12, Noise, which has the following scope:

Standards, specifications, and terminology in the field of acoustical noise pertaining to methods of measurement, evaluation, and control, including biological safety, tolerance, and comfort, and physical acoustics as related to environmental and occupational noise.

At the time this standard was submitted to Accredited Standards Committee S12, Noise, for final approval, the membership was as follows:

P.D. Schomer, *Chairman*
R.D. Hellweg, *Vice Chairman*
S.B. Blaeser, *Secretary*

Abbot Laboratories	D. Walton
	B. Muto (<i>Alt.</i>)

B.M. Brooks	W.W. Lang	L.C. Sutherland	R.W. Young

Working Group S12-42, Classroom Acoustics, which assisted Accredited Standards Committee S12, Noise, in the preparation of this standard, had the following membership:

D. Lubman and L.C. Sutherland, *Co-Chairmen*

K.L. Anderson	R.D. Godfrey	P.B. Nelson	A. Seltz
R.E. Apfel	J.J.C. Gould	M.T. Nixon	N.T. Shade
J.S. Bradley	W.H. Hannon	J. Olson	L.L. Semesky
B.M. Brooks	R.D. Hellweg	S.W. Payne	G.W. Siebein
D.C. Bruck	M.R. Hodgson	K.S. Pearsons	J.J. Smaldino
A.J. Campanella	K.A. Hoover	R.J. Peppin	S.D. Soli
R.C. Coffeen	S. Inglis	J. Pope	D.L. Sorkin
D. Collings	C.D. Johnson	D. Queen	N.D. Stewart
C.C. Crandell	D.L. Johnson	R. Randall	L. Thibault
T.J. DuBois	H.F. Kingsbury	L. Redden	B.D. Tinianov
G. Ehrlich	J.G. Lilly	S.I. Roth	E.A. Wetherill
S.L. Ehrlich	J. Lyons	K.P. Roy	S.J. Woodhead
J. Erdreich	H.L. Merck	M.E. Schaffer	W.A. Yost
D. Fagen	R. Moulder		

Suggestions for the improvement of this standard are welcome. They should be made in writing to Accredited Standards Committee S12, Noise, in care of the Standards Secretariat, Acoustical Society of America, 35 Pinelawn Road, Suite 114E, Melville, New York 11747. Telephone: +1 631 390 0215; FAX: +1 631 390 0217; e-mail: asastds@aip.org

American National Standard

ACOUSTICAL PERFORMANCE CRITERIA, DESIGN REQUIREMENTS, AND GUIDELINES FOR SCHOOLS

0 Introduction

Good acoustical qualities are essential in classrooms and other learning spaces in which speech communication is an important part of the learning process. Excessive background noise or reverberation in such spaces interferes with speech communication and thus presents an acoustical barrier to learning. With good classroom acoustics, learning is easier, deeper, more sustained, and less fatiguing. Teaching should be more effective and less stressful with good acoustical characteristics in a classroom. There can be more verbal interaction and less repetition between teacher and students when spoken words are clearly understood. Although all those in a classroom, including teachers and adult learners, will benefit, special beneficiaries are young children and persons with hearing, language, speech, attention deficit, or learning disabilities. As discussed further in annex A, conformance to this standard will improve the quality of education by eliminating acoustical barriers for all students and teachers, including those with communication disabilities. Good design and attention to detail throughout the construction or renovation process can ensure conformance to the requirements of this standard.

1 Scope, purpose, and applications

1.1 Scope

1.1.1 This standard provides acoustical performance criteria and design requirements for classrooms and other learning spaces. Annexes are included to provide information on good design and construction practices, installation methods, and optional procedures to demonstrate conformance to the acoustical performance and design requirements of this standard. This standard seeks to pro-

vide design flexibility without compromising the goal of obtaining adequate speech intelligibility for all students and teachers in classrooms and learning spaces within the scope of this standard.

1.1.2 Acoustical performance criteria are specified in this standard by limits on maximum one-hour A-weighted and C-weighted background noise levels and limits on maximum reverberation times. An objective of these performance criteria is to achieve a level of speech that is sufficiently high relative to the background noise level for listeners throughout the classroom or learning space. However, a requirement for the relative difference between speech levels and levels of background noise, usually referred to as the signal-to-noise ratio, is not within the scope of this standard.

1.1.3 The control of background noise levels in this standard is achieved, in part, by specifying the minimum noise isolation for school building elements. Noise isolation requirements are applicable to the following two types of intrusive noise.

- Noise that intrudes into the classroom or learning space from sources outside of the school building envelope. These noise sources include vehicular traffic, aircraft, industrial plants, and activity in schoolyards or from grounds maintenance. (Schools usually can control only the schoolyard and grounds-maintenance noise sources. However, when a new school site is under consideration, sound from commercial, industrial and transportation noise sources can be taken into account.)
- Noise that originates within the school building and intrudes into the classroom through classroom walls and partitions, floor-ceiling assemblies and ventilation systems. Interior noise sources can be isolated through the proper design and construction of the school building and by noise control measures applied to the building services and utilities.

1.1.4 This standard does not apply to noise generated within a classroom by its occupants. Occupant-generated noise sources include voices and the sounds of classroom activities such as the moving of chairs. Furthermore, this standard does not apply to the noise from portable or permanent built-in equipment used during the course of instruction, such as audiovisual equipment and computers. However, the background noise generated by occupants and instructional equipment can seriously degrade communication or speech intelligi-

bility in learning spaces. Recommendations are given in B5 in annex B for noise control of instructional equipment. Recommendations for background noise assessment procedures are given in E3.2.1 in annex E for such equipment. The teacher can reduce classroom activity noise directly through appropriate controls. This activity noise can also be reduced indirectly in classrooms with acoustical qualities that conform to this standard since a quiet classroom with low reverberation tends inherently to encourage children to lower the level of their voices and the sounds of their activity.

1.1.5 The following annexes are provided to support this standard.

- Annex A: Rationale for the acoustical performance criteria in this standard. (Informative)
- Annex B: Design guidelines for noise control for building services, utilities, and instructional equipment. (Informative)
- Annex C: Design guidelines for controlling reverberation in classrooms and other learning spaces. (Informative)
- Annex D: Design guidelines for noise isolation between adjacent learning spaces within a school building and noise isolation by the building facade. (Informative)
- Annex E: "Good architectural practices" and procedures to verify conformance to the standard. (Normative but Informative if conformance is not to be verified.)
- Annex F: Potential conflict between the acoustical requirements of this standard and indoor air quality (IAQ) and multiple chemical sensitivity (MCS). (Informative)
- Annex G: Cautionary remarks on using supplemental descriptors for evaluating noise in classrooms and other learning spaces. (Informative)

1.2 Purpose

This standard is intended to help school planners and designers provide the acoustical qualities necessary for good speech communication between students and teachers in classrooms and other learning spaces without the use of electronic amplification systems.

1.3 Applications

1.3.1 This standard applies to classrooms and other core learning spaces of small-to-moderate size with volumes not exceeding 566 m³ (20 000 ft³) and to ancillary learning spaces of any volume.

Core learning spaces larger than the above volume limit shall be considered ancillary spaces for purposes of this standard. The standard does not apply to special-purpose classrooms, teleconferencing rooms, special education rooms, such as those for severely acoustically-challenged students or other spaces, such as large auditoria that have unique or more stringent acoustical requirements. Conformance to the requirements of this standard should be considered to be a minimum goal for the acoustical qualities of such spaces, excluding auditoria. The standard does not provide recommendations for electronic amplification or for electronic aids for persons with hearing impairment.

1.3.2 The acoustical performance criteria and design requirements of this standard apply during the design and construction of all new classrooms or learning spaces of small-to-moderate size as specified in 1.3.1. As far as is practicable, these acoustical performance criteria and design requirements also apply during the design and reconstruction of all renovated classrooms and learning spaces. However, the noise reduction and reverberation control principles in this standard also apply to larger classrooms or learning spaces. Thus, while this standard does not necessarily apply to all college and university classrooms or lecture halls, business or professional educational institutions or other adult education centers, acoustical performance criteria and design requirements similar to those in this standard may still pertain to such applications. Appropriate application of this standard to such alternative learning spaces is encouraged.

1.3.3 This standard is intended for use by school building specialists, educators, and parents. The information in annexes B, C, and D is intended for direct application by school design professionals including architects.

2 Normative references

The following standards contain provisions that, through reference in this text, constitute provisions of this American National Standard. At the time of approval of this standard by the American National Standards Institute, Inc. (ANSI), the editions indicated were valid. Because standards are revised from time to time, users should consult the latest revision approved by the American National Standards Institute (ANSI), International Electrotechnical Commission (IEC), and the American Society

for Testing and Materials (now called ASTM International). For the purposes of this standard, the use of the latest revision of a referenced standard is not mandatory. Information on recent editions is available from the ASA Standards Secretariat and ASTM International.

3 Definitions

The following definitions apply for the purposes of this standard.

3.1 General terms

3.1.1 classrooms and other learning spaces. Locations within buildings where students assemble for educational purposes.

3.1.1.1 core learning spaces. Spaces for educational activities where the primary functions are teaching and learning and where good speech communication is critical to a student's academic achievement. These spaces include, but are not limited to, classrooms, (enclosed or open plan), instructional pods or activity areas, group instruction rooms, conference rooms, libraries, offices, speech clinics, offices used for educational purposes and music rooms for instruction, practice and performance.

3.1.1.2 ancillary learning spaces. Spaces where good communication is important to a student's educational progress but for which the primary educational functions are informal learning, social

interaction or similar activity other than formal instruction. These areas include, but are not limited to, corridors, cafeterias, gymnasias, and indoor swimming pools.

3.1.2 acoustical privacy. Pertains to the acoustical attenuation between spaces that is needed to prevent conversation in one space from being understood in an adjacent space.

3.1.3 conforming learning space. Any classroom or other learning space for which the acoustical performance criteria and design requirements conform to this standard.

3.2 Terms relating to acoustical performance and design

The following terms are defined in a simplified form. Complete technical definitions are provided in ANSI S1.1.

3.2.1 noise level or sound level. Generic terms employed interchangeably throughout this standard to represent the frequency-weighted sound pressure level of an airborne sound. This descriptor is used to express the magnitude of a sound in a manner related to how the ear perceives this magnitude. Noise level or sound level is expressed in decibels, unit symbol dB.

3.2.1.1 A-weighted sound level. Sound pressure level measured with a conventional frequency weighting that roughly approximates how the human ear hears different frequency components of sounds at typical listening levels for speech. The A-weighting (see ANSI S1.4 or IEC 61672-1) attenuates the low-frequency (or low-pitch) content of a sound. A-weighted sound level is expressed in decibels, unit symbol dB.

3.2.1.2 C-weighted sound level. Sound pressure level measured with a conventional frequency weighting (see ANSI S1.4 or IEC 61672-1) that does not significantly attenuate the low-frequency (or low-pitch) content of a sound. C-weighted sound level is expressed in decibels, unit symbol dB.

3.2.1.3 one-hour-average A-weighted or C-weighted sound level. Level of the time-mean-square A-weighted or C-weighted sound pressure averaged over a one-hour period. One-hour-average sound level is expressed in decibels, unit symbol dB.

3.2.1.4 yearly average day-night average sound level. Level of the time-mean-square A-weighted

sound pressure averaged over a one-year period with 10 dB added to sound levels occurring in each nighttime period from 22:00 hours to 07:00 hours. Yearly average day-night average sound level is expressed in decibels, unit symbol dB.

3.2.2 background noise level. Sound in a furnished, unoccupied learning space, including sounds from outdoors, building services and utilities operating at their maximum levels. For the purposes of this standard, this excludes sound generated by people within the building or sound generated by temporary or permanent instructional equipment.

3.2.2.1 steady background noise. Noise from building services and utilities and from outdoor noise sources that is fairly constant over time.

3.2.2.2 unsteady background noise. Time varying noise from transportation sources, such as aircraft, vehicle traffic or from other time varying outdoor or indoor noise sources. Unsteady background noise varies substantially over time.

3.2.3 reverberation. An acoustical phenomenon that occurs in an enclosed space, such as a classroom, when sound persists in that space as a result of repeated reflection or scattering from surfaces enclosing the space or objects in the space, such as chairs or cabinets.

3.2.3.1 reverberation time. A measure of the amount of reverberation in a space and equal to the time required for the level of a steady sound to decay by 60 dB after it has been turned off. The decay rate depends on the amount of sound absorption in a room, the room geometry, and the frequency of the sound. Reverberation time is expressed in seconds, unit symbol s.

3.2.4 sound absorption and reflection. Acoustical phenomena that occur whenever sound strikes a surface. Absorbed sound is the portion of the sound energy striking the surface that is not returned as sound energy. Reflected sound is the remaining portion that bounces off the surface. The magnitude of the reflected sound in a room is determined by the amount of sound absorption at the surfaces, the room geometry, and the frequency of the sound. As distance from a sound source in a classroom increases, the sound is increasingly dominated by reflected sound.

3.2.4.1 sound absorption coefficient. A measure of the ability of a material to absorb sound and equal to the ratio of the intensity of the ab-

sorbed sound to the intensity of the incident sound. The sound absorption coefficient of a material normally varies with frequency. It ranges from about 0.2 to about 1.0 for sound-absorbing materials, to less than 0.05 for a smooth, painted concrete floor. Sound absorption coefficients measured in a laboratory (that is, in a reverberation room) can be larger than 1.0 because of test method and sample size effects.

3.2.5 acoustic isolation. A measure of the decrease in sound level (attenuation) when sound passes from one room to another, such as from one side of a wall to the other side. The passage of sound may be via an airborne path or via a structureborne path.

3.2.5.1 attenuation of airborne sound. Attenuation of sound passing through walls or ceilings, between spaces within a building, or through roofs or external walls. The attenuation of airborne sound depends on the sound reduction through these elements, on their size, on sound leakage around their periphery, on the sound absorption in the receiving space, and on the frequency of the sound.

3.2.5.2 sound transmission class. Single number rating for the acoustic attenuation of airborne sound passing through a partition or any other building element such as a wall, roof, or door as measured in an acoustical testing laboratory following accepted industry practice, abbreviation STC. A higher STC rating provides more sound attenuation through a partition.

3.2.5.3 noise isolation class. Single number rating of the noise isolation between two enclosed spaces that are acoustically connected by one or more paths, abbreviation NIC. The rating is derived from the difference in sound levels between two spaces. A higher NIC rating provides more noise isolation between the two spaces.

3.2.5.4 impact insulation class. Single number rating for the attenuation, measured in an acoustical testing laboratory, of structureborne sound through floor or floor-ceiling assemblies from floor impacts into the space below, abbreviation IIC. A higher IIC rating provides more impact sound attenuation into the space below.

3.2.5.5 field impact insulation class. Single number rating of the structureborne noise isolation provided by a floor or floor-ceiling assembly, abbreviation FIIC. The rating is derived from

Table 1 — Maximum A-weighted steady background noise levels and maximum reverberation times in unoccupied, furnished learning spaces

Learning space ^{a)}	Maximum one-hour -average A-weighted steady background noise level ^{b,c)} dB	Maximum reverberation time for sound pressure levels in octave bands with midband frequencies of 500, 1000, and 2000 Hz s
Core learning space with enclosed volume < 283 m ³ (< 10 000 ft ³)	35	0.6
Core learning space with enclosed volume > 283 m ³ and ≤ 566 m ³ (> 10 000 ft ³ and ≤ 20 000 ft ³)	35	0.7
Core learning spaces with enclosed volumes > 566 m ³ (20 000 ft ³) and all ancillary learning spaces	40 ^{d)}	e)

a) See 3.1.1.1 and 3.1.1.2 for definitions of core and ancillary learning spaces.

b) See 4.3.1 for limits on unsteady (time varying) background noise levels.

c) See 4.3.2 for other limits on background noise from building services and utilities including C-weighted steady background noise levels.

d) When corridors are used solely for conveyance of occupants within the school building and structured learning activities do not occur, the A-weighted steady background noise level limit for such corridors may be increased to 45 dB. The use of corridors for formal learning purposes should be avoided.

e) See C3.3 in annex C for recommendations on control of reverberation in these spaces.

the sound levels measured in the receiving room when a standard tapping machine is operating on the floor assembly in the source room above. The higher the FIIC rating, the more the impact noise isolation between the two spaces.

4 Acoustical performance criteria and noise isolation design requirements and guidelines

4.1 Introduction

Acoustical performance criteria and design requirements are contained in the following sub-clauses. The performance criteria shall apply to classrooms and other core learning spaces and to ancillary learning spaces. For purposes of this standard it shall be assumed that the learning spaces are furnished consistent with their use and the building is unoccupied with doors and windows closed. Acoustical design requirements for minimum noise isolation apply only to fully enclosed classrooms and learning spaces.

4.2 Performance criteria for background noise and reverberation time

The one-hour-average A-weighted steady background noise level and the reverberation times shall not exceed the limits specified in table 1. The limits for the background noise shall apply for the following conditions:

- 1) for the noisiest continuous one-hour period during times when learning activities take place;
- 2) exterior and interior noise sources are operating simultaneously;
- 3) interior sources are operating as defined in 4.3.2; and
- 4) portable and permanent (built-in) instructional equipment, such as computers and audio-visual equipment, are turned off.

While designing to conform to both acoustical performance criteria in table 1 is required, conformance to the background noise level criterion is the more important of the two. When optional conformance testing is carried out, the tolerances specified in 4.7 reflect this relative importance.

4.3 Background noise levels

4.3.1 Unsteady background noise from transportation noise sources. School facilities should be sited and designed to limit the noise levels inside learning spaces from transportation noise sources, such as aircraft, road vehicles and trains. (See D2.3 in annex D for further guidance on outdoor-indoor noise isolation and school siting.)

The limits on A-weighted background noise levels in table 1 shall be increased by 5 dB when the noisiest hour is dominated by transportation noise and the following conditions apply to the A-weighted SLOW time-weighted background noise level. For core learning spaces with enclosed volumes not greater than 566 m³ (20 000 ft³), this level does not exceed 40 dB for more than 10% of this noisiest hour. For core learning spaces with enclosed volumes greater than 566 m³ (20 000 ft³) and for ancillary learning spaces, this level does not exceed 45 dB for more than 10% of this noisiest hour. (See E3.7.2 in annex E for a measurement method for this evaluation.)

4.3.2 Background noise from building services and utilities. Steady background noise from HVAC systems and other building services and utilities operating simultaneously shall conform to the requirements of table 1 for all operating modes (for example, cooling, heating, ventilating, and dehumidifying) and at the maximum operating conditions (for example, maximum fan speed with all lights on). Unsteady background noise levels from plumbing systems (for example, toilets and bathing rooms) operating at their noisiest condition, shall also conform to the limits in table 1 taking into consideration their normally limited operating time within any one hour. (See annex B for guidelines on control of noise from HVAC systems, building services, and utilities.)

4.3.2.1 Limits on steady C-weighted background noise levels from building services and utilities. The maximum one-hour-average C-weighted steady background noise levels from the combination of HVAC systems, lighting, and other building services and utilities operating simultaneously shall not exceed the limits on A-weighted steady background noise levels in table 1 by more than 20 dB.

4.3.2.2 Limits on disturbing sounds from building services and utilities. Disturbing sounds, such as rumble, hum, buzz, whine, hiss, or whistle, from HVAC systems and other building services

and utilities shall be controlled so as to not interfere with speech communication or be distracting or annoying to the occupants of the learning spaces.

4.3.2.3 Limits on time-varying noise levels from building services and utilities. The A-frequency-weighted and SLOW time-weighted noise level at any usable location in a room, from HVAC systems and other building services operating as specified in 4.3.2 shall not vary by more than 3 dB during any 5-s period. This shall be measured with a sound level meter conforming to at least the Type 2 requirements of ANSI S1.4 or the class 2 requirements of IEC 61672-1. Such time-varying noise shall be considered to be caused by the building systems and services, unless the noise is clearly recognized as being produced by transportation noise sources, such as road traffic or aircraft, addressed in 4.3.1.

4.3.3 Background noise from instructional equipment. For this standard, noise from instructional equipment is not included in the steady background noise. However, control of such noise, especially that from permanent built-in instructional equipment, should be carefully addressed in the planning stages for new and renovated schools. (See B5 in annex B for guidance on applicable noise control measures for such instructional equipment.)

4.4 Reverberation times

The maximum allowable reverberation times in unoccupied, furnished core learning spaces are specified in table 1 for core learning spaces with enclosed volumes of not more than 566 m³ (20 000 ft³). Design guidelines for controlling reverberation time in learning spaces of all sizes and for selection and proper certification for any acoustical materials applied to control this reverberation are presented in annex C.

4.5 Noise isolation design

The first and most cost effective step in achieving good noise isolation between learning spaces and other spaces in a school is accomplished in the facility planning stage. This includes optimizing the location of noisy spaces and activities to protect sensitive learning spaces. Where this is not possible, adequate noise isolation is needed.

4.5.1 Need for noise isolation. The acoustical performance criteria for background noise levels in

Table 2 — Minimum STC ratings required for single or composite wall, floor-ceiling, and roof-ceiling assemblies that separate an enclosed core learning space from an adjacent space

Adjacent space			
Other enclosed or open plan core learning space, speech clinic, health care room and outdoors ^{c)}	Common use and public use toilet room and bathing room	Corridor, ^{a)} staircase, office or conference room ^{a,b)}	Music room, mechanical equipment room, ^{d)} cafeteria, gymnasium, and indoor swimming pool
50	53	45	60

- ^{a)} For corridor, office, or conference room walls containing doors, the basic wall, exclusive of the door, shall have an STC rating as shown in the appropriate column in this table. The entrance door shall conform to the requirements of 4.5.5.
- ^{b)} When the need for acoustical privacy is critical, the minimum STC rating of the partitions around an office or conference room shall be increased to 50.
- ^{c)} An STC rating of 50 is the minimum for the exterior walls and roofs of a core learning space. However, this rating does not ensure conformance to the background noise limits in table 1 for noise from major outdoor noise sources. See D2.3 in annex D for further guidance on the selection of appropriate STC ratings.
- ^{d)} When the adjacent space is a mechanical equipment room containing fans circulating 140 m³/min. (5000 ft³/min.) or more, the minimum STC rating shall be 60. When the fan circulation is less than this rate, the STC rating may be as low as 45 providing the maximum A-weighted steady background noise level in the adjacent core learning space does not exceed 35 dB. The minimum STC rating shall include the effect of entry door(s) into the mechanical equipment room.

4.2 and 4.3 apply to unoccupied facilities. However, in occupied facilities, activity noises generated in one space can be transmitted through walls, floors, ceilings, and doors to adjacent learning spaces, thus contributing to the overall background noise level in those spaces. Adequate sound isolation is required to limit noise transmission between core learning spaces and adjacent spaces in occupied facilities. The minimum STC ratings of table 2 and table 3 are intended to provide this noise isolation for normal activities in adjoining spaces.

Certain educational styles (such as open plan and group learning) intentionally avoid the use of full enclosures between learning groups. Sometimes, partial height sound barriers or no barriers at all separate adjacent learning groups. Adequate noise isolation between adjacent learning groups cannot be assured unless each learning group is fully enclosed by ceiling-height sound barriers. Because of the inherent low noise isolation, partially enclosed or unenclosed learning spaces are not recommended when good speech communication is desired.

In occupied multistory educational facilities, the transmission of impact noise through the floor of the room above to the learning space below also contributes to the overall background noise level.

To limit impact noise disturbances in learning spaces, this standard also provides minimum impact insulation class (IIC) design requirements for the floor-ceiling assemblies above learning spaces for multistory educational facilities.

As discussed further in D1 in annex D, the noise isolation requirements of this standard are similar in concept to those in existing national and international building codes.

4.5.2 Noise isolation design requirements. In this standard, noise isolation is specified by the minimum values for the STC and IIC ratings for single and composite building elements that may provide acceptable noise isolation for learning spaces. Selection of these minimum ratings, achieved during architectural design, is the basis for limiting the transmission of background noise from external and interior sources into an enclosed learning space. After construction, a field measurement may be made to verify the noise isolation achieved [see 4.6 (3)].

When high noise isolation is required, as for music rooms, flanking of sound along common floors, walls, and roofs can become a limiting factor unless controlled with proper breaks in sound transmission paths or other similar treatments. There are many publications that provide details on de-

Table 3 — Minimum STC ratings recommended for single or composite wall, floor-ceiling and roof-ceiling assemblies separating an ancillary space from an adjacent space

Receiving ancillary Learning space	Adjacent space Corridor, ^{a)} staircase, common use and public use toilet and bathing room ^{b)}	Music room	Office or conference room ^{a)}	Outdoors ^{e)}	Mechanical equipment room, ^{f)} cafeteria, gymnasium or indoor swimming pool
Corridor	45	60 ^{c)}	45 ^{d)}	45 ^{e)}	55 ^{e)}
Music room	60	60	60	45	60
Office or conference room	45	60	45 ^{d)}	45	60

- a) For corridor, office or conference room walls containing entrance doors, the STC rating of the basic wall, exclusive of the door, should be 45. The entrance door should conform to the requirements of 4.5.5.
- b) The STC rating for an ancillary space/toilet partition does not apply when the toilet is private and connected to a private office. An STC rating higher than 45 may be required for separating a quiet office or conference room from a common use or public use toilet or bathing room.
- c) When the corridor will not be used as an ancillary learning space, the minimum STC rating may be reduced to not less than 45 or to not less than 40 for an exterior wall. Use of corridors as ancillary learning spaces should be avoided when they are located next to the noisy spaces indicated in the table by the high STC ratings.
- d) When the need for acoustical privacy is critical, the STC rating should be increased to 50.
- e) See D2.3 in annex D for further guidance on the selection of appropriate STC ratings.
- f) NOTE d) of table 2 applies except that the STC rating may be as low as 40 providing the maximum A-weighted steady background noise level in the adjacent ancillary learning space does not exceed 40 dB.

sign and construction of separating partitions that may achieve the required STC ratings. Annex D provides guidelines and references for such noise isolation design and construction.

4.5.3 Sound transmission class (STC) ratings

4.5.3.1 Core learning spaces. The minimum STC ratings in table 2 shall be employed for the acoustical design of wall, floor-ceiling and roof assemblies that separate enclosed or open plan core learning spaces from adjacent spaces. When the assembly includes two or more elements, such as doors or windows, the STC of this composite assembly also shall conform to the requirements of table 2.

Composite assemblies are walls, floor-ceiling and roof-ceiling constructions composed of more than one element (for example, a wall with a door, window, or penetrations by HVAC ducts or other services). (See NOTE a) to table 2 for special requirements for doors in corridor, office or conference room walls.)

Walls and floor-ceiling assemblies may not maintain their design STC rating if penetrations or openings for piping, electrical devices, recessed

cabinets, soffits, or heating, ventilating or exhaust ducts are unsealed. For this reason, all penetrations in sound-rated partitions shall be sealed and treated to maintain the required ratings. The STC rating requirements of table 2 shall also be employed for the design of temporary partitions that subdivide a learning space.

4.5.3.2 Ancillary learning spaces. Recommendations are given in table 3 for STC ratings for partitions (that is, walls and floor-ceiling assemblies) that enclose an ancillary learning space or that separate two ancillary spaces. When the partition includes two or more elements, such as doors, windows, or penetrations of the partition for HVAC ducts or other services, the STC of this composite construction also should conform to the recommendations of table 3.

4.5.4 Composite partitions. The required minimum STC ratings in table 2 apply to single or composite partitions. Basic wall assemblies (except those identified in NOTE a) for table 2) which contain doors or windows with STC ratings less than those given in table 2, will require higher STC ratings to conform to the required minimum STC ratings of the composite construction. This design

technique is also recommended for partitions enclosing the ancillary learning spaces covered by table 3. A method for estimating the STC rating of composite partitions is provided in D2.4 in annex D.

4.5.5 Entry doors into classrooms and other core learning spaces. To conform to the STC requirements of table 2 for composite walls, entrance doors into classrooms or other core learning spaces would be expected to have laboratory STC ratings of 30 or more in their operable condition. The STC rating for interior entry doors into, or between, music rooms shall be not less than 40. The location of classroom entry doors across a corridor should be staggered to minimize noise transmission between these classrooms.

Provisions should be made to ensure that the perimeter seals of sound rated doors are well maintained. Seals for entrance doors should be inspected and adjusted, as necessary, every six months. The gaskets of door seals should never be painted.

4.5.6 Impact Insulation Class (IIC) rating. The floor-ceiling assemblies of normally occupied rooms located above core learning spaces shall have IIC ratings of at least 45 and preferably 50. If a room below is an ancillary learning space, the floor-ceiling assembly shall have an IIC rating of at least 45. These IIC ratings shall apply without carpeting on the floor in the room above. In new construction, gymnasias, dance studios or other high floor impact activity, shall not be located above classrooms or other core learning spaces. For refurbishment of existing structures, if it is not possible to avoid such an incompatible condition, the IIC rating of the separating floor-ceiling assembly shall be at least 70 when located above a core learning space with an enclosed volume not greater than 566 m³ (20 000 ft³); 65 when located above a core learning space with an enclosed volume greater than 566 m³ (20 000 ft³); and 65 when located above an ancillary learning space. Clause D2.5.1 in annex D provides further guidance on impact noise isolation.

4.6 Conformance to acoustical performance criteria and noise isolation design requirements

It is recommended that conformance to the acoustical performance criteria and noise isolation design requirements be verified by test. However, this standard does not require testing to demon-

strate conformance. When optional tests are performed to verify conformance with the requirements and recommendations of this standard, the following procedures shall be followed.

1) Tests to demonstrate conformance to the limits on background noise levels in table 1, 4.3.1, and 4.3.2.1 shall be performed in accordance with the procedures in E3 of annex E. If necessary, appropriate tests shall be performed to demonstrate conformance with the limits on disturbing or time varying noise from building services and utilities given in 4.3.2.2 and 4.3.2.3. (See E3.7.3 in annex E.)

2) Conformance to the limits on reverberation times in table 1 shall be verified by calculation or by measurement procedures in conformance, or equivalent, to those in E4 of annex E.

3) Conformance to the minimum sound transmission class (STC) design requirements of table 2 and the design recommendations of table 3 shall be verified by field determination of the noise isolation class (NIC) as described in E5.1 in annex E. However, it shall be considered unnecessary to verify conformance to these noise isolation design requirements and recommendations if conformance to the noise limits of table 1 is demonstrated for the noisiest hour when learning takes place.

4) Conformance to the impact insulation class (IIC) requirements of 4.5.6 shall be verified by the field testing procedures in E5.2 in annex E.

4.7 Conformance tolerances

When conformance testing or evaluation is performed, conformance to the requirements and recommendations of this standard is demonstrated if each of the following is achieved. No additional tolerances shall be allowed for the test methods or instruments used for such demonstrations except as specified in this subclause.

1) The measured A-weighted steady or unsteady background noise levels do not exceed the limits specified in table 1 and 4.3.1, respectively, by more than 2 dB. The C-weighted steady background noise levels do not exceed the limits in 4.3.2.1 by more than 2 dB.

2) Mean reverberation times, if calculated, do not exceed the limits in table 1 or, if measured, do not exceed the limits in table 1 by more than 0.1 s.

3) All separating walls and floor-ceiling assemblies have NIC ratings that are not less than a rating 5 points below the required STC rating in table 2 or

the recommended rating in table 3. For example, for a partition between a classroom and a speech clinic, conformance to the minimum STC rating of 50 in table 2 is achieved if the NIC rating is not less than 45.

4) All floor-ceiling assemblies separating occupied spaces from learning spaces below have a field impact insulation class (FIIIC) rating that is not less than a rating 5 points below the design requirement specified in 4.5.6.

Annex A (Informative)

Rationale for acoustical performance criteria

A1 Introduction

The school classroom is an environment in which spoken language communication facilitates and enables students to learn essential academic, social, and cultural skills. Thus, the classroom serves as a communication channel for learning and should be free of acoustical barriers. This informative annex defines the perceptual, educational, and developmental rationale for the acoustical performance criteria specified in table 1 of this standard. These rationales allow determination of the signal-to-noise ratio and reverberation time that can ensure most children, adult learners, and teachers full and equal access to spoken communication within the classroom. The acoustical performance criteria in the standard are derived from empirical studies of classroom noise and reverberation and their effects on speech communication.

A1.1 Educational rationale

Intensive and continuous learning of social, intellectual, and communication skills occurs throughout childhood. A wide range of educational research studies [A1]* has shown that learning is predicated on the ability to communicate with spoken language, and that language input and language proficiency form the bases for most cognitive skills. Additionally, other research [A2] has shown that perception of spoken language provides the foundation for the ability to read and write. Communication with spoken language is essential to most classroom learning activities. Typically, as much as 60% of these activities involve students listening to and participating in spoken communications with the teacher and other students. The central role of spoken language in classroom learning underscores the need for a clear communication channel accessible to all students and teachers.

A1.2 Perceptual rationale

Communication with spoken language can occur successfully only when speech intelligibility is high. Research in speech perception [A3] has found that when the background noise is very low, speech intelligibility depends in part on the absolute sound level of the speech, and in part on the absence of excessive reverberation.

A1.3 Speech intelligibility in background noise

Most speech communication in classrooms occurs in the presence of background noise. When background noise is present, intelligibility depends on the sound pressure level of the speech and also on the level of the speech relative to the level of the noise, that is, the signal-to-noise ratio (SNR) [A4]. The sound levels of both the speech and noise are expressed as A-weighted sound levels in decibels. The relative speech to noise level, or SNR, expressed in decibels, is the sound level of the speech alone in the presence of background noise minus the sound level of the background noise.

Intelligibility increases as the SNR increases, either by raising the speech level or by decreasing the noise level. Speech perception research [A5] has shown that individuals with hearing impairments, speech and language disorders, or limited English proficiency require more favorable signal-to-noise ratios than individuals without these impairments or disorders to achieve high levels of speech intelligibility.

A1.4 Speech intelligibility in reverberant environments

Classrooms are enclosed spaces in which sound produces reverberation. Reverberation times in

*[AX] designates reference [AX] in the bibliography at the end of this annex.

excess of 0.4 s to 0.6 s reduce speech intelligibility both in quiet and in noise.

When both background noise and excessive reverberation are present, their effects on speech intelligibility are additive for individuals with normal speech, language, and hearing abilities. Speech perception research [A4, A6] has shown that individuals with impaired speech, language, and hearing abilities require signal-to-noise ratios that are at least 3 dB more favorable to offset their susceptibility to the negative effects of reverberation, as compared with individuals without impairments.

A1.5 Selective acoustical barriers to learning produced by background noise and reverberation

If spoken communication in the classroom becomes inaudible or unintelligible for some students and teachers because of excessive background noise or reverberation, a clear communication channel is no longer accessible to these children, creating a selective acoustical barrier to learning. Neither the child's ability to understand in quiet nor the adult teacher's ability to understand in the noisy classroom is a good predictor of when such barriers might exist. This difficulty in prediction is also exacerbated by a young child's unawareness of these barriers to learning.

A1.6 Scholastic achievement and the classroom acoustical environment

The link between the acoustical barriers in the classroom and the scholastic achievement of students has been evaluated in studies supporting the objectives of this standard. The reading scores of 2nd to 6th grade children in a school exposed to noise from a nearby elevated urban train track [A7, A8] were compared in quieter and noisier classrooms. The students, comparable in all respects, were receiving the same type of instruction. However, the children in the lower grades and noisier classrooms were three to four months behind in reading scores relative to those in the quieter classrooms and as much as 11 months behind for the higher grades. After a subsequent reduction of the track noise by 3 to 8 dB, the reading scores in the noisy classrooms were still approximately one year behind those in the quiet classrooms.

A major, controlled study of noise effects on scholastic achievement [A9] was carried out in 81

classrooms in 15 socio-economically matched Los Angeles schools located different distances from freeways. These differences caused the traffic-noise-generated indoor background noise to differ by up to 19 dB between the noisiest and quietest classrooms. Reading and math grade-equivalent scores evaluated for English-proficient students in 3rd and 6th grade classes, showed a decrease of approximately 2.2 years between the noisiest and quietest schools for the 6th grade classes and 0.7 years for the 3rd grade classes. This prominent noise effect on grade differences in scholastic achievement is believed the result of either differences in teaching style between grades or, more insidious, a possible cumulative, compounded effect of poor acoustics on learning as a student progresses through school.

A study of 13 schools in the United Kingdom [A10] compared their acoustical environment and corresponding speech communication conditions and teacher satisfaction before and after sound-absorbing treatment of the ceilings. After treatment, the average A-weighted background noise level in the unoccupied classrooms dropped from 45 dB to 40 dB reflecting the decrease in reverberant background noise level. The average reverberation time in the unoccupied rooms dropped from 0.7 to 0.4 seconds. The acoustically treated classrooms were favored by the teachers and pupils, who reported a greater ease of communication and increased student performance.

A2 Developmental rationale

Young children are more susceptible than adults to the effects of background noise and reverberation on communication with spoken language. Because of this susceptibility, young children also require more favorable classroom signal-to-noise ratios and reverberation times to achieve the same level of speech intelligibility as adults do. Developmental status, linguistic and cognitive proficiency, temporary hearing impairments, and early receptive and expressive language disorders are all factors that affect the greater susceptibility of young children to background noise and reverberation. For example, in a longitudinal study [A11] of preschool children in acoustically-treated or non-treated rooms in a child-care center, the children in the treated rooms scored higher in number-letter-word recognition after one year of reduced noise exposure than their cohorts in the non-treated rooms.

A2.1 Developmental status

Speech communication in unfavorable listening conditions is a complex, high-level task requiring a level of neurological maturity that is usually achieved only by 13 to 15 years of age. Consequently, young children may require more favorable signal-to-noise ratios and shorter reverberation times than older children require. Speech perception research [A12] has shown that 6-year-old children with normal hearing and normal language proficiency require signal-to-noise ratios 2 dB more favorable than 15-year-old children to achieve the same level of speech intelligibility. The 15-year olds, however, required the same signal-to-noise ratios as adults. In quiet listening conditions, the adults and both age groups of children had good speech intelligibility.

A3 Hearing impairment

Young children are also more susceptible to temporary conductive hearing impairment caused by ear infection (otitis media) than adults. Demographic research [A13] has identified otitis media as the most common medical disorder in young children, with an estimated incidence as high as 25% to 30% among kindergarten and first grade children. Other research [A14] has found an incidence greater than 10% of mild high-frequency sensorineural hearing impairment among children 6 to 19 years of age. Signal-to-noise ratio improvements of 3 dB to 5 dB together with increases in absolute speech sound levels of 10 dB to 30 dB are necessary for children with these impairments to achieve the same level of speech intelligibility in classrooms with high background noise.

A4 Language proficiency and language disorders

Children with expressive and receptive language disorders may also require more favorable signal-to-noise ratios to achieve good intelligibility, as compared with children without these disorders. Research studies have shown, for example, that children with language disorders have 10% to 40% poorer speech intelligibility in background noise than children without these disorders, despite comparable results in quiet environments. Children for whom English is not the first or primary language may have limited English proficiency. These children are often learning English in school at the same time that they are learning the regular academic curriculum.

Limitations in vocabulary and in the ability to "fill in the blanks" when partial communication occurs in difficult listening situations have been shown to reduce intelligibility for children with limited English proficiency [A15], again despite normal intelligibility in quiet environments. These children may require 2 to 5 dB more favorable signal-to-noise ratios in difficult listening situations to achieve the same level of intelligibility as children with normal English proficiency.

A related speech disorder problem caused by poor classroom acoustics stems from the increased frequency of voice impairments and their consequences for communication. In noisy or reverberant classrooms, teachers are more likely to have to raise their voices. The results are higher incidences of voice impairment among teachers and children have greater difficulty hearing verbal instruction presented by voice-impaired teachers in such noise or reverberation.

A5 Determining appropriate acoustical performance criteria and noise isolation design requirements

The acoustical performance criteria for this standard are expressed in table 1 in terms of background noise levels and reverberation times. Noise isolation design requirements for this standard are given in table 2, in terms of sound transmission class (STC) ratings for enclosed learning spaces, despite the fact that the rationale for these criteria and requirements is based on absolute and relative levels of speech. The terminology of the standard is necessary because speech levels are difficult to prescribe or standardize. However, the research literature on classroom speech sound levels can be used to specify the expected range of speech sound levels seen throughout a classroom. These sound levels, together with knowledge of the signal-to-noise ratios and reverberation times necessary for high intelligibility, were used to determine the requirements for acceptable background noise levels and reverberation times for unoccupied, furnished classrooms in table 1. The background noise level criteria were, in turn, used to determine acceptable STC ratings for walls, ceilings, and floors, in table 2, that will prevent noise from adjacent occupied enclosed spaces from exceeding the background noise level criteria in the classroom.

A5.1 Classroom speech levels

Research studies [A16] of sound levels for conversational speech and teachers' classroom speech [A17] show for the latter, the average A-weighted sound level is 67 dB at 1 m in a quiet classroom. In typical classrooms with little reverberation, speech sound levels in the rear of the classroom may be as low as 50 dB. The criteria for background noise levels in this standard assume minimum speech sound levels will be 50 dB anywhere in the classroom.

A5.2 Background noise levels

The 35 dB acoustical performance criteria for steady classroom background noise levels in table 1 were based on the assumption that a signal-to-noise ratio of at least +15 dB was necessary to ensure that noise will not be a barrier to learning within a classroom. Assuming a minimum speech level of 50 dB, a signal-to-noise ratio of at least +15 dB will always be achieved if the background noise level does not exceed 35 dB. The choice of +15 dB for the signal-to-noise ratio was based on several considerations. The American Speech-Language-Hearing Association [A18] recommends at least a +15 dB signal-to-noise ratio in classrooms to ensure that children with hearing impairments and language disabilities are able to achieve high speech intelligibility.

In addition, the research literature summarized in this annex also supports a signal-to-noise ratio of +15 dB.

Normal adults typically require 0 dB signal-to-noise ratios for high speech intelligibility when listening to simple and familiar speech material for short periods of time. An additional 2 dB is needed to compensate for neurological immaturity; an additional 5 dB is required to compensate for sensorineural and conductive hearing losses; an additional 5 dB is required for limited English proficiency and language disorders; and an additional 3 dB is required to compensate for the effects of excessive reverberation. These additional requirements for classrooms total 15 dB over that of normal adults, or a signal-to-noise ratio of +15 dB. This conclusion does not include any further increase in the signal-to-noise ratio that may be associated with the fact that children in the lower grades may be listening to unfamiliar speech material.

A5.3 Reverberation times

According to available research data, the effects of reverberation on speech intelligibility are controlled primarily by reverberation times at the three frequencies specified in table 1: 500, 1000, and 2000 Hz. Based on this research, it was assumed that reverberation times of 0.6 s, or less, in small and mid-sized classrooms and 0.7 s, or less, in larger classrooms will not degrade speech intelligibility excessively as long as signal-to-noise ratios of +15 dB or better are maintained. (The reverberation times in table 1 are given for unoccupied, furnished spaces. For occupied spaces, the reverberation times are expected to be 0.1 s to 0.2 s less than those in table 1.) These signal-to-noise ratios will be achieved if the background noise performance criteria also are satisfied. Thus, the acoustical performance criteria for both steady background noise levels and reverberation times should be satisfied simultaneously to ensure the elimination of acoustical barriers to classroom learning.

Annex B (Informative)

Design guidelines for noise control for building services, utilities, and instructional equipment

B1 Introduction

HVAC systems and other building services and utilities are complex systems of mechanical, electrical, and plumbing components supplied by many different manufacturers. This observation is particularly true for most HVAC systems designed for specific projects. Noise from these building systems can be generated and transmitted to a room in a wide variety of ways. Responsibility for providing an adequate noise control design that will allow conformance to the background noise level limits in table 1 resides with the architect and the architect's design subcontractors. During construction, responsibility for implementing the noise control design for each element of the building services may rest with each individual subcontractor, but the general contractor is likely to have overall re-

sponsibility to ensure that the design and implementation conforms to the background noise level limits in table 1.

B2 HVAC noise control

Specific limits on the maximum allowable A-weighted and C-weighted background noise level from HVAC equipment are given in 4.3. To achieve these limits, an HVAC system should be designed with noise control in mind. The following are some of the minimum features that should be employed for HVAC systems intended for any learning facility.

1) Unducted systems should not be employed since the sound they produce is inherently unable to conform to the background noise level criteria in table 1.

2) All grilles and diffusers (air devices) should be selected to have a catalog Noise Criteria (NC) rating of NC 18 or less for a single diffuser, providing the NC catalog ratings are based on a correction of 10 dB for sound absorption in the room. [B1]

NOTE Noise Criteria (NC) is a single number rating of room noise based on comparison of the octave-band sound pressure level spectrum of a noise with standardized octave-band sound pressure level contours that include low-frequency sound (see annex G).

3) Airflow velocities in trunk ducts should not exceed 4.1 m/s (800 ft/min). Branch ductwork sizes should match the air device's duct connection size. Duct silencers will be required inside the air-handling unit or in the main supply and return air ducts in most systems.

4) All ductwork should be fabricated and installed so as to achieve a low static pressure loss in accordance with procedures in the Sheet Metal & Air-Conditioning Contractors National Association (SMACNA) for HVAC System Duct Design, [B2]. To achieve the rated performance of air diffusers, the plenum depth should be the equivalent of at least three to four diameters of the duct going to the diffuser.

5) All rotating equipment and equipment with static pressure control dampers should be 3.3 m (10 ft), or farther if possible, from the classroom. HVAC fan equipment serving more than one classroom should be farther from the classrooms than equipment serving only one classroom.

6) Centrifugal fans with airfoil-shaped blades should be used in most cases in order to achieve the background sound levels required for the learning spaces. Centrifugal fans with forward curved blades should be avoided (especially with central air distribution systems) because this fan design typically generates excessive low-frequency noise when the total static pressure is greater than 2 inches of water.

7) Ductwork serving adjacent learning spaces should include sound attenuators or sound-absorbing duct lining (if required), or both, to reduce crosstalk through the duct system. The attenuation should be sufficient to preserve the noise isolation between the adjacent learning spaces.

8) To minimize HVAC noise transmission into core learning spaces, variable air volume (VAV) boxes and fan-powered boxes should not be located over these spaces. Instead, the elements should be lo-

cated over less sensitive spaces, which may include corridors.

The above guidelines are examples of the many noise control provisions that may be needed when designing an HVAC system. Before finalizing any HVAC noise control design, considering the very large number of HVAC systems types that may be employed for schools, the facility designer or the responsible subcontractor should consult one or more references such as those listed in clause B7. The ASHRAE Handbooks, [B3-B5] are especially helpful to assist in achieving an HVAC system design that will conform to the required minimum level of steady background noise. HVAC manufacturers should be able to provide useful design or noise-rating information for their systems or components [B6]. References [B7], [B8] and [B9] provide further guidance on noise control for HVAC systems and other building services.

B3 Noise control considerations for electrical equipment and systems

Significant background noise in a learning space can be produced by electrical equipment and its installation. Two such sources of noise are electrical fixtures and light fixture ballasts. Light fixtures with low-noise ballasts should be used in learning spaces to assist in conforming to the requirements of table 1 for background noise levels. Improper installation of electrical or cable boxes can degrade sound isolation between rooms. For single stud walls, electrical outlet boxes on opposing walls should never be in the same stud space. For dual-stud walls, the boxes should be separated by at least 0.6 m (24 inches). If back-to-back electrical boxes are necessary in double stud walls, either of the following methods should be used. The boxes should be enclosed in full gypsum board enclosures that do not contact the framing of the other row of studs and have all joints sealed with caulking or both boxes should be of the vapor-barrier type that are properly caulked and sealed.

B4 Plumbing systems noise control

Water flow noise from plumbing systems can be a significant contributor to the background noise level in a learning space. To minimize noise from plumbing fixtures and piping located adjacent to core and ancillary learning spaces, consideration should be given to the following installation details.

- 1) Run piping above corridor ceilings, not above learning spaces.
- 2) Locate restrooms away from classrooms.
- 3) Use cast iron waste water pipes, when possible. Plastic piping may require special care during installation to ensure quiet operation and should be wrapped with one or more layers of sound-attenuating material or, for plastic waste pipe, wrapped with sound-absorbing material and boxed in with gypsum wallboard.
- 4) Isolate all water piping from the building walls and structure using foam rubber wrapping or resilient clamps and hangers.
- 5) When it is necessary for a plumbing wall chase to be adjacent to a learning space, the wall should employ double stud construction [with a minimum 2.5 cm (1 inch) gap between the two rows of studs] with two layers of gypsum board on the classroom side and sound-absorbing insulation batts in both stud cavities.
- 6) Reduce the pressure of the supply water as much as possible and employ trapped-air water-hammer arrestors for water supply pipes serving flush or solenoid valve fixtures to reduce water hammer noise.
- 7) Use water siphon jet fixtures instead of blowout fixtures.
- 8) Inspect all plumbing installations for conformance to the noise control features before sealing the walls.

B5 Noise control for instructional equipment used in a classroom

As stated in 1.1.4, the background noise from portable or permanent, built-in equipment used during the course of instruction, such as audio-visual equipment or computers, is not within the scope of this standard. Cooling fans or other internal rotating components usually generate this noise. Because this noise can increase the background noise level in learning spaces, this equipment should be carefully selected and located to minimize its noise impact on the learning process. Except for computers, standards for the acoustical emission characteristics (for example, sound power level) of such equipment are not currently available.

Such instructional equipment, when operating, should be located as far as possible from students

or placed in noise-isolating enclosures. This procedure is especially important and practical for built-in audio-visual systems or overhead projectors. For such built-in equipment, a design goal should be to ensure that its operation will not cause the total one-hour average background noise level to exceed the limits specified in table 1 while HVAC systems and other building services and utilities are also operating.

The designer of the noise-control features should actively seek to determine whether potentially noisy instructional equipment is planned for permanent or long-term installation in a noise-sensitive instructional space. If so, appropriate noise isolating enclosures should be included in the classroom design planning.

The background noise level in a learning space containing a large number of computers, each with its own cooling fan, may be well above the background noise limits in table 1. In such learning spaces, special consideration should be given to noise control by selection of low-noise computers and the addition of more sound-absorbing treatment than needed to conform to the reverberation criteria in table 1 in order to minimize the reverberant level of this background noise. Sound-absorbing partial barriers may be needed between computer stations.

B6 Conforming to the limits for background noise level

Conforming to the noise level criteria specified in table 1 and the design techniques discussed in this annex may require coordinated action by the architects for design of the school building, the general building contractor, the school-facility design staff, the equipment suppliers, and a person with professional experience in building noise control technology.

Selection of a person experienced in building noise control technology is the ultimate responsibility of the owner or designer of the educational facility. However, such a person should be able to provide evidence of professionally recognized expertise in noise-control technology for building services, utilities, and equipment, or be employed by a firm with the same professionally recognized expertise.

The fact that a project has a person trained in building noise control technology on the design team does not ensure conformance to the provi-

sions of this standard. Workmanship and the quality of products used on the project are also major factors in achieving the required acoustical environment in all learning spaces. The best design can be negated by poor workmanship and use of products that do not conform to published performance specifications.

Manufacturers of school building services equipment, utilities (for example, HVAC and lighting) and instructional equipment usually can supply noise emission levels for their products. This information should be evaluated carefully during the equipment selection process.

Annex C (Informative)

Design guidelines for controlling reverberation in classrooms and other learning spaces

C1 Introduction

The amounts and locations of sound absorption treatments needed to limit reverberation are important considerations for good acoustical characteristics in learning spaces. Excessive reverberation can reduce the understanding of spoken words. Conversely, too much sound-absorbing treatment, especially in dedicated lecture rooms, can reduce beneficial early sound reflections causing speech levels from a talker to fall off rapidly with distance and thereby reduce speech intelligibility for distant listeners. This annex provides design guidelines for the control of reverberation in learning spaces by the addition of sound-absorbing materials. The guidelines are intended to assist

in achieving conformance to the reverberation time criteria in table 1.

C2 Procedure to estimate the amount of sound-absorbing material needed to achieve the design goal for reverberation time

The first step in developing an estimate of the minimum required area of acoustical treatment for installation in a learning space is to apply the Sabine formula [C1]. According to this formula, the minimum total sound absorption A needed to achieve a reverberation time of T_{60} seconds or less in a room of enclosed volume V is given by:

$$A \geq kVT_{60} \quad (\text{C.1})$$

The constant $k = 0.161$ s/m when volume V is in cubic meters and the sound absorption A is in square meters. Constant $k = 0.049$ s/ft when volume V is in cubic feet and sound absorption A is in square feet.

Next, the total sound absorption is broken down into the sum of the products of the surface area S_i of each such sound-absorbing surface and the sound absorption coefficient α_i for this surface. That is, the total sound absorption A is given by the summation over all treated surfaces as expressed by the following relation:

$$A = \alpha_1 S_1 + \alpha_2 S_2 + \alpha_3 S_3 + \dots + \alpha_i S_i + A_R \quad (\text{C.2})$$

where A_R is the residual sound absorption. A default value of A_R equal to 15% of the floor area accounts for the acoustically untreated room surfaces (for example, the untreated walls, ceiling, and bare, uncarpeted floor) and for the furnishings (for example, tables, chairs, and shelves (see C3.5)). For a carpeted room, a value for A_R of 20% of the floor area is recommended as a conservative default design value.

Alternatively, the designer can set A_R equal to 13% of the floor area plus the product of the carpet surface area and its sound absorption coefficient. The latter may vary from a minimum of less than 0.1 at 500 Hz to as high as 0.65 at 2000 Hz, depending on the type and thickness of the carpet and its underlayment. Many references, such as those listed in the bibliography to this annex, provide tables of sound absorption coefficients for different acoustical materials, including carpet, at different frequencies.

These same references may be used to provide alternative sound absorption coefficients for other surfaces in place of the preceding default assumptions. Tabulations of the sound absorption per table or chair are available from these references. Their values may be used if these furnishings are comparable to those intended for the learning space.

For best accuracy in calculations of reverberation time, it is recommended that laboratory-certified sound absorption coefficients be used. These are normally available from acoustical material manufacturers, (see C2.1).

Next, the values of α_i and S_i for the proposed materials and surface areas are substituted into equa-

tion (C.2). If necessary, the choices of material and material areas are adjusted until equation (C.1) is satisfied. The minimum total sound absorption is calculated from application of equation (C.1) for frequencies of 500 Hz, 1000 Hz, and 2000 Hz.

The process described above can be simplified substantially when only one type of sound-absorbing material is to be installed and A_R is assumed to be 15% of the floor area.

The volume V of the learning space can be expressed as the product of floor area S_f and average ceiling height H . Using equations (C.1) and (C.2) and a residual absorption of 15% of the uncarpeted floor area, it is straightforward to construct a table of the minimum required surface area S_1 as a percentage of the floor area for maximum reverberation times of 0.6 s and 0.7 s from table 1. The variables in the table are the sound absorption coefficient α_1 of the acoustical treatment and average ceiling height H .

With the assumptions described above, the entries in table C.1 for the minimum surface area of acoustical treatment S_1 as a percentage of floor area S_f were calculated from the following expression.

$$100(S_1/S_f) \geq 100\{[(kH/T_{60}) - 0.15]/\alpha_1\} \quad (\text{C.3})$$

where k is the constant employed in equation (C.1).

As shown in table C.1, for either of the two reverberation times, the required minimum surface area of acoustical treatment increases as the ceiling height increases and as the sound absorption coefficient decreases. The table shows the need to apply acoustical treatment to the walls as well as the ceiling for rooms with high ceilings and low sound absorption coefficients. Two examples illustrate application of the data in the table.

Example 1.

A rectangular core learning space has dimensions of 40 ft long by 25 ft wide by 9 ft high. It is planned to install sound-absorbing material only on the ceiling. The enclosed volume is $(40 \times 25 \times 9) = 9000$ ft³. From table 1, for this enclosed volume, the maximum reverberation time is 0.6 s at each of the three specified frequencies. Manufacturer's data indicate that the proposed acoustical ceiling material has sound absorption coefficients of 0.65, 0.80, and 0.90 at 500 Hz, 1000 Hz, and 2000 Hz, respectively.

From table C.1, for the smallest absorption coefficient of 0.65 and the 9 ft ceiling height, the required minimum area of treatment is 90% of the floor area of $40 \times 25 = 1000 \text{ ft}^2$, or 900 ft^2 . This leaves 10% of the ceiling area free for lighting and other services. If the allowance for lighting area is inadequate, some acoustical treatment may have to be installed on the walls.

NOTE 1. While the required sound absorption should be confirmed at each of the three frequencies, it will generally be found that conformance to the reverberation-time requirement of table 1 at 500 Hz will also ensure conformance at the two higher frequencies.

NOTE 2. If the manufacturer's sound absorption data are between the sound absorption coefficients listed in the first column of table C.1, the required treatment area can be computed by interpolation in the table. For example, if the lowest sound absorption coefficient for example 1 were 0.67 instead of 0.65, the relative treatment area for the ceiling would be $90\% \times (0.65/0.67)$ or 87% of the floor area or 870 ft^2 instead of 900 ft^2 .

A similar table can be constructed from equation (C.3) for a carpeted floor by changing the default value for A_p/S_f from 0.15 for uncarpeted floors to 0.2 for carpeted floors.

Example 2.

For the same core learning space as in example 1, it is now considered necessary to improve the intelligibility of speech in this lecture-type classroom. In accordance with the guidance in C3.1.2, additional sound-absorbing material is to be installed as a ring around the walls near the ceiling. The sound-absorbing ceiling treatment is to be of the same material as for example 1, but the proposed acoustical wall treatment has manufacturer-stated absorption coefficients of 0.45, 0.60, and 0.70 at 500 Hz, 1000 Hz, and 2000 Hz, respectively.

In this case, as a working assumption, assume that the ceiling is to provide 60% of the total sound absorption while the remaining 40% of the total sound absorption is provided by the wall treatment.

Therefore, the ceiling treatment area should be 60% of the 900 ft^2 determined for example 1 or $0.6 \times 900 = 540 \text{ ft}^2$. According to table C.1, for the 9 ft ceiling and the smallest sound absorption coefficient of 0.45 for the wall treatment, the minimum required surface area of wall-treatment material would be 130% of the floor area of 1000 ft^2 if it

were the only material used. However, under the assumptions, only 40% of that area is required or $0.4 \times 1.3 \times 1000 = 520 \text{ ft}^2$. For the room perimeter of 130 ft, the height of the wall treatment would need to be 4 ft on each of the four walls or 44% of the total wall area.

In summary, 540 ft^2 of ceiling treatment material and 520 ft^2 of wall treatment material would be required for the core learning space to conform to the 0.6 s reverberation time limit in table 1 while providing good intelligibility of spoken words. Other distributions of ceiling and wall treatment areas could be evaluated if it were considered that too much of the available wall area was devoted to sound-absorbing material.

C2.1 Sound absorption coefficients and related design considerations

The sound absorption coefficients for all acoustical materials supplied for the project should be determined in accordance with ASTM C423 [C2]. The learning facility owner's representative should request from the acoustical materials contractor(s):

- a) appropriate certification that all material(s) have been tested in full accordance with ASTM C423 and
- b) a table of the laboratory-certified sound absorption coefficients at 500, 1000 and 2000 Hz for the materials employed (see E4.2.1 in annex E). The mounting condition employed for these tests should be identified and, preferably, should be the same as the as-installed mounting configuration. The designer should recognize that when the cavity depth behind the acoustical material in a laboratory configuration mounting is greater than for the as-installed depth, the installed low-frequency sound absorption coefficients are usually lower than those for the laboratory tests.

Tradeoffs between the sound-absorption coefficients and the surface areas of treatment are allowed if the tradeoffs result in the same or lower reverberation times than those specified in table 1 for each of the three frequencies.

When selecting acoustical materials to meet the reverberation time performance criteria in table 1, it is prudent to allow for sufficient surface area coverage using sound absorption coefficients that fall in the lower range that alternative suppliers may provide. This procedure helps insure that the properly certified material from the lowest bidder is adequate.

Table C.1 — Minimum surface area of acoustical treatment for different sound absorption coefficients, ceiling heights, and reverberation times.

		(a) Reverberation time, T_{60} , of 0.6 s Ceiling height, H , ft								
Sound absorption coefficient, α_1	8	9	10	11	12	13	14	15	16	
	Ceiling height, H , m									
	2.44	2.74	3.05	3.35	3.66	3.96	4.27	4.57	4.88	
Minimum area of sound-absorbing material as a percentage of the floor area										
0.45	112	130	148	167	185	203	221	239	257	
0.50	101	117	134	150	166	183	199	215	232	
0.55	92	107	121	136	151	166	181	196	211	
0.60	84	98	111	125	139	152	166	179	193	
0.65	78	90	103	115	128	141	153	166	178	
0.70	72	84	95	107	119	130	142	154	166	
0.75	67	78	89	100	111	122	133	144	154	
0.80	63	73	83	94	104	114	124	135	145	
0.85	59	69	79	88	98	107	117	127	136	
0.90	56	65	74	83	92	101	111	120	129	
0.95	53	62	70	79	88	98	105	113	116	
1.00	50	59	67	75	83	91	100	108	116	

NOTE Sound absorption coefficients stated by a manufacturer to be greater than 1.0 based on laboratory tests may be taken as equal to 1.00 for purposes of this annex.

		(b) Reverberation time, T_{60} , of 0.7 s Ceiling height, H , ft								
Sound absorption coefficient, α_1	8	9	10	11	12	13	14	15	16

1.00	41	48	55	62	69	76	83	90	97	

NOTE Sound absorption coefficients stated by a manufacturer to be greater than 1.0 based on laboratory tests may be taken as equal to 1.00 for purposes of this annex.

C3 Further design guidance

C3.1 Location of the absorbing material

C3.1.1 General Classrooms. In cases where there is no fixed lecture position for the teacher, and when ceiling heights are less than about 3 m (10 ft), the best option is to place most if not all of the sound-absorbing material on the ceiling. For ceiling heights greater than 3 m (10 ft), which is discouraged for classrooms, an increasing amount of the sound-absorbing material will have to be on the walls as the wall height increases above 3 m. If nearly all of the installed sound-absorbing material is on the ceiling, then it is prudent to introduce furnishings such as bookshelves of adequate height to assure that sound waves traveling across the room are scattered in the direction of the sound-absorbing acoustical ceiling.

C3.1.2 Lecture-type classrooms. Speech intelligibility studies [C3] have shown that, for lecture-type classrooms, it is best to ring the upper wall and ceiling with sound-absorbing material. This configuration enhances reflections to and from the back of the room, as well as back and forth across the room, thus promoting good speech communication between teacher and student and vice versa, as well as among students. This arrangement also enhances better communication for group discussions and pod formats where the teacher moves around the room.

For classrooms that have a relatively fixed teacher position, the sound-absorbing material should not be placed just above and in front of the teacher's position because that position would reduce the level of the teacher's voice at the positions of the students.

C3.2 Mounting of acoustical treatment in classrooms

Ceiling acoustical treatment is normally suspended from the ceiling with an air space specified by the architect. The height of the air space may, or may not, be the same as the 40 cm (16 inch) air space commonly used by manufacturers to achieve the sound absorption coefficients that are measured by a testing laboratory. As long as the minimum air space required for installing a lay-in ceiling exists, the actual sound absorption at frequencies of 500 Hz and higher should be not less than the published values. Experienced professionals should be consulted when reverberation at frequencies less than 500 Hz is a major concern.

Wall-mounted materials should be installed, as recommended by the manufacturer, with clips or glue to the wall surface or be fastened to added spacers to achieve the stated sound absorption coefficients.

C3.3 Reverberation control for ancillary and large core learning spaces

For ancillary spaces, such as corridors, gymnasias, cafeterias and large core learning spaces [volume > 566 m³ (> 20 000 ft³)] sound-absorbing material should be installed to reduce noise caused by the activities of occupants, as well as to control reverberation. The amount of acoustical treatment will vary widely, but corridors should generally have a total surface area of sound-absorbing material that is not less than 50% of the ceiling area and up to 75% if possible; 75% treatment area is recommended for corridors with high traffic or noisy lockers.

A measure of the sound absorption coefficient of acoustical materials is provided by a single number rating called the noise reduction coefficient (NRC), [C4, C5]. For cafeterias and for large core learning spaces with ceiling heights up to 3.7 m (12 ft), a suspended ceiling with an NRC of 0.70 or higher should be used for the full ceiling area exclusive of the area required for lights and ventilation grilles. Higher NRC ratings should be considered especially for ceiling heights less than 3.7 m. When the ceiling height is greater than 3.7 m (12 ft), especially if greater than 4.6 m (15 ft), a more detailed analysis by experienced personnel may be required to provide adequate control of reverberation. In any event, as suggested by table C.1, wall treatment should be included for such high-ceiling rooms. Depending on the amount of wall treatment, the ceiling NRC or treated area might then be reduced when some of the wall area is covered by sound-absorbing material. When permitted within sanitation restrictions, similar acoustical treatment should be employed in food-serving and food-preparation areas.

NOTE The Noise Reduction Coefficient is equal to the arithmetic mean of the sound absorption coefficients at 250, 500, 1000, and 2000 Hz, rounded to the nearest multiple of 0.05. The NRC of acoustical material should not be used for design or calculation of reverberation time for core learning spaces for purposes of this standard.

For rooms with high ceilings, such as gymnasias, the installation of acoustical treatment on the walls

is important to minimize reverberant build-up of noise level. Absence of any acoustical treatment on the walls of high-ceiling rooms can make the material on the ceiling less effective than expected.

Guidance is available in the references listed in the bibliography in C5 for many other architectural acoustics design objectives applicable to reverberation control in ancillary spaces and large core learning spaces. These objectives include but are not limited to:

- providing suitable reverberation times for large core learning spaces and dual-purpose ancillary spaces such as a cafeteria also used as an auditorium (e.g. - Ref. C5, C6, or C7), and
- including additional sound-absorbing material on the walls in corridors connecting noisy rooms to quieter areas of the school and in corridors with busy foot traffic or noisy lockers.

C3.4 Carpeting in classrooms

Carpeting in a classroom (for example, in an area where young children sit on the floor together for a story) can help substantially to reduce background noise in the classroom from chair and foot impacts or scuffing. Carpeting can also attenuate the transmission of this impact noise to the room below. The alternative use of neoprene chair leg tips should be considered as a way to help minimize chair-shuffling noise without the use of carpeting. See annex F for discussion of indoor air quality (IAQ) and multiple chemical sensitivity (MCS) issues for carpeting.

Carpeting alone usually does not provide enough sound absorption for classrooms since it is generally poor at low frequencies, even when newly installed. (See text following Equation C.2 for further details.)

C3.5 Absorption of furnishings and occupants

Calculations of reverberation times for learning spaces assume typical furnishings such as chairs, tables, and storage cabinets. A sound absorption equal to 5% of the floor area, already included in the residual absorption term A_R in equation C.2, is a conservative approximation for the sound absorption of these furnishings. These furnishings are normally floor-mounted and thus their quantity and hence their sound absorption will tend to be proportional to the floor area. The 5% figure is con-

sistent with limited experimental data comparing the reverberation for furnished and unfurnished classrooms.

The sound absorption of learning space occupants was considered in setting the limits on reverberation time in table 1 and should not be included in any calculations for the reverberation time of an unoccupied space. The sound absorption provided by an occupant is approximately equal to 0.55 m^2 (6.0 ft^2) for an adult student and about 20% less for a high school student and 40% less for an elementary grade student [C4].

C4 Guidelines for good acoustics in large classrooms and lecture rooms

This standard does not specify performance criteria or design requirements for enclosed learning spaces larger than 566 m^3 ($20\,000 \text{ ft}^3$). However, limited additional recommendations and design guidelines for larger rooms and other spaces in educational facilities, aside from those in C3.3, are given in this subclause.

Large lecture rooms generally differ physically and functionally in many ways from classrooms found in elementary and secondary schools. The teacher-student configuration tends to be fixed; the size of the room can vary greatly, sometimes accommodating hundreds of students. The shape of the room may vary from a traditional rectangular shape; HVAC systems usually have much greater capacities; and speech reinforcement systems as well as other fixed audiovisual facilities are common in such spaces.

For unamplified speech, beneficial sound-reflecting surfaces, especially over the teacher-lecturer, are necessary to assure adequate speech sound levels in the back of the room with relatively uniform distribution of the sound of spoken words. If the teacher-student configuration is fixed, beneficial reflections can be obtained with sound-reflecting surfaces placed above the lecturer, sometimes extending over the audience, on the ceiling, or sidewalls. Because of the larger room volumes, reverberation times usually are greater than in small classrooms, with values of 0.7 s to 1.1 s in occupied rooms not uncommon. To assure less variability in the reverberation time with changes in occupancy, it is always desirable to have sound-absorbing upholstered chairs in small auditoria. To minimize echoes, the back wall is often made sound absorbing, or is tilted to avoid sending reflections back toward the source, or both.

Because of the complexity of the design of large lecture rooms, experienced professionals should be consulted to ensure that the design and its implementation achieve the acoustical objectives of this standard.

Further guidance for detailed design considerations of lecture rooms can be found in a number of sources including [C1, C4-C11] listed in the bibliography.

Annex D (Informative)

Design guidelines for noise isolation

D1 Introduction

This annex provides informative design guidelines for noise isolation between learning spaces and between a learning space and other interior or exterior spaces. Application of these design guidelines will assist, but not guarantee, achieving conformance to the background noise level limits in table 1. The STC and IIC ratings in 4.5 are intended to provide a practical means of achieving this conformance. All acoustical aspects of the design and construction should therefore be consistent with this intent. In support of this intent, since many finished component assemblies involve the work of more than one building trade, architectural specifications should refer to noise control and isolation measures in all applicable sections. After completion of construction, on-site testing may

also be needed when it is necessary to verify conformance to the STC or IIC ratings of 4.5, (see E5.1 in annex E).

The noise isolation provided by wall or ceiling elements depends on both the materials used and the installation practices and may be strongly affected by sound leakage at joints and penetrations and unintended flanking paths around these elements. When a high degree of noise isolation is required, as for music rooms, flanking of sound transmission through common floors, walls, and ceilings can limit the isolation actually achieved unless proper steps are taken in the design and construction.

The noise isolation requirements of this standard are similar in concept to requirements incorporated in several existing national and international building codes. Examples include: a) Appendix Chapter 12 Division II-Sound Transmission Con-

trol of the 1997 Uniform Building Code (UBC), b) Section 1206 of the 2000 International Building Code, and c) Standard SSTD 8-87 of Southern Building Code Conference International (SBCCI). All of these prescribe minimum STC ratings for separating walls and floor-ceiling assemblies. Except for the SBCCI code, they also prescribe minimum IIC ratings for floor-ceiling assemblies. The requirements for this standard differ from those in the above codes because the application for the space is different and, in many cases, have more stringent acoustical design requirements.

D2 Noise isolation

D2.1 Noise isolation between interior spaces

Table 2 specifies the required minimum STC ratings for interior and exterior walls surrounding enclosed learning spaces. The table presents design requirements for STC ratings of typical wall constructions where the wall is continuous to the floor below or floor-ceiling system above, with all penetrations adequately sealed, (see the guidance in ASTM E497 [D1]). General design guidance on noise isolation is provided in many texts and reports on building noise control including references D2 to D15.

D2.2 Noise isolation of open-plan classrooms

The low noise isolation that is inherent with open-plan classrooms is generally well below the design requirements in table 2. Therefore, this standard emphasizes that open-plan classroom design should be strongly discouraged since the resulting background noise levels in a core learning space as a result of activities by students in other core learning spaces within an open classroom setting are highly likely to exceed the background noise limits in table 1. The poor acoustical performance of open-plan systems has a negative impact on the learning process and tends to defeat any teaching methodology advantages that may accrue from their use.

D2.3 Outdoor-to-indoor noise isolation

D2.3.1 Outdoor-to-noise environments. There is no single answer for the proper amount of noise isolation to include in the design to shield a learning space from industrial or transportation outdoor noise sources. Each situation is unique with regard to distance to, and the extent and characteristics of, industrial sources, local traffic, or other transportation noise sources. The best solution to out-

door-to-indoor noise isolation design is to measure the current, or predict the future, noise levels of external sources at the proposed locations for facades. The next step is to determine the necessary outdoor-to-indoor noise level reduction to achieve the required interior background noise level in table 1. (See D2.3.3 for one approximate method.) It is good design practice to allow a margin of safety to account for uncertainties, including the possibility that current outdoor sound levels may increase in the future. For predictions of external noise levels, widely accepted models for assessing industrial or transportation noise sources will normally be available to environmental planners or acoustical consultants. For some sites, maps or contours of the current or projected outdoor noise environment may be available from local planning departments.

Selection of materials and acoustical design for the exterior envelope of a school building should consider these measured or predicted noise levels. Knowledge of these levels can assist in achieving adequate acoustical design features to attenuate the outdoor noise levels and ensure that the interior background levels do not exceed the limits in table 1.

D2.3.2 Selecting sites for learning facilities. As recommended by ANSI S12.9/Part 5 [D10], learning facilities should not be located at sites where the yearly average day-night average sound level exceeds the following limits with corresponding construction methods:

- 60 dB to 65 dB for conventional construction methods for the learning facility, providing the external walls are designed to a minimum STC rating of 50 consistent with the minimum ratings in table 2 and table 3;
- 65 dB to 75 dB if the external shell of the learning facility is designed to provide adequate noise isolation in order to conform to the limits in table 1 for background noise levels (see D2.3.3).

Under no conditions should a new learning facility be located at a site where the yearly average day-night average sound level exceeds, or is predicted to exceed, 75 dB.

D2.3.3 Approximate STC ratings to achieve a desired outdoor-to-indoor noise level reduction. Given the limits on background noise levels from table 1 and the external noise environments established by one of the procedures outlined in

Table D.1 — Approximate difference between the minimum STC rating required for building envelope components and the required outdoor-to-indoor noise level reduction

Fenestration %	(STC rating of walls and roofs) minus (outdoor-to-indoor noise level reduction) dB	(STC rating of doors and windows) minus (outdoor-to-indoor noise level reduction) dB
1 to 25	15	6
26 to 70	20	11

NOTES

- a) Fenestration is the percentage of the total wall and roof surface area that consists of windows, doors, and other openings. For rooms without a roof, it is the percentage of the total wall area made up of windows, doors, and other openings.
- b) The values for the nominal STC rating minus the outdoor-indoor noise level reduction in columns 2 and 3 are based on the expectation that the dominant outdoor noise source is vehicular traffic. If other sources dominate, adjustments may be needed. For example, if aircraft noise is the dominant source, the minimum required STC rating may increase by about 2 dB.

D2.3.1 and D2.3.2, the recommended STC rating for the wall, roof, door, and window elements of the school building envelope may be estimated from the data in table D.1.

Table D.1 gives the approximate difference in decibels between the minimum STC rating of the exterior elements of a learning space and the required outdoor-to-indoor noise level reduction for two ranges of the relative area of the fenestration in the envelope. While only an approximation, the data in the table may be used for initial estimates of the STC rating required for the components of the exterior envelope of the structure.

NOTE Outdoor-to-indoor noise level reduction is the difference in A-weighted sound level between a specified outdoor sound field and the resulting A-weighted sound level in the room abutting the facade or facade element of interest. It can be measured in accordance with ASTM E966 [D9] where it is called "outdoor-indoor level reduction".

As an example, assume that the dominant source of exterior noise is road traffic and that the maximum one-hour-average A-weighted noise level is 65 dB at the nearest exterior classroom wall facing the traffic. To conform to the background noise limit inside the classroom of 35 dB from table 1, the nominal outdoor-to-indoor noise level reduction would have to be $65 - 35$ or 30 dB. According to table D.1, for an exterior wall with fenestration greater than 25%, the nominal STC rating of the

exterior walls would have to be at least $30 + 20$ or 50. The STC rating of the windows would have to be at least $30 + 11$ or 41.

To obtain estimates of the required STC ratings that are better than those obtained from application of table D.1 would require an assessment of the frequency spectrum of the long-term average exterior noise level. Also needed is the frequency-dependent sound transmission through the walls, roof, windows, and doors that are planned for the envelope of the school building (see ref. D8, D9).

D2.4 STC ratings for composite elements of a wall or roof assembly

STC ratings for a composite of several elements in a structural assembly may be estimated by application of the data in table D.2. Table D.2 may be employed to determine the STC rating of two different building elements such as walls, doors and windows with STC ratings, STC (1) and STC (2), where STC (1) is greater than STC (2) and with corresponding surface areas S_1 and S_2 .

Enter table D.2 in the column across the top with the difference in the STC ratings rounded to the nearest 3 dB. Then go down to the row indicated in the left-most column to the range that includes the area S_2 as a percentage of the total area ($S_1 + S_2$) of both elements. At the intersection of the row and column, find the correction to subtract from

Table D.2 — Correction data for estimating the STC rating of a two-element composite building assembly.

S2/(S1+S2) ×100%	STC (1) rating minus STC (2) rating, dB									
	3	6	9	12	15	18	21	24	27	30
	Correction to subtract from STC (1) to obtain the STC rating of the composite assembly, dB									
0 to 0.2	0	0	0	0	0	0	0	1	2	3
>0.2 to 0.5	0	0	0	0	0	1	1	3	4	6
>0.5 to 1	0	0	0	0	1	2	3	4	7	9
>1 to 2	0	0	0	1	2	3	4	7	9	12
>2 to 5	0	0	1	2	3	5	7	10	12	15
>5 to 10	0	1	2	3	5	7	10	13	16	19
>10 to 20	1	2	3	5	7	10	13	16	19	20
>20 to 30	1	2	4	7	9	12	15	18	21	24
>30 to 40	1	3	5	8	11	14	17	20	23	26
>40 to 60	2	4	7	9	12	15	18	21	24	27
>60 to 80	2	5	8	10	13	16	19	22	25	28
>80 to 100	3	6	9	12	15	18	21	24	27	30

STC (1) to yield the estimate for the STC rating of the composite assembly. For more than two elements in a composite assembly, repeat the process by combining the STC of the composite assembly consisting of the first two elements with the STC of the third element, and so on.

As stated in NOTE a) to tables 2 and 3, the STC rating for the walls of a corridor, office, or conference room containing entrance doors excludes these entrance doors. The design and anticipated STC rating for such entrance doors is given in 4.5.5.

D2.5 Isolation from impact noise or vibrating machinery

D2.5.1 Design guideline for impact noise isolation for floor-ceiling assemblies. For learning spaces in multi-story school buildings, classrooms in lower stories may need to be protected from the noise of impacts on the floor of rooms immediately above. Impact noise may arise from footfalls or the scuffing of furniture in the room above. Impact noise can be reduced sufficiently by ensuring that the floor-ceiling system has an adequately high Impact Insulation Class (IIC) rating. Installing carpet on the floor will almost always ensure an IIC rating greater than 50 but may not reduce the low-frequency impact sounds sufficiently. It is good practice to design the floor-ceiling assemblies to achieve a minimum IIC 50 rating without carpeting above classrooms or other core learning spaces. For this purpose a permanent resilient underlayment may be required to isolate the finished floor from the structural floor system.

To achieve high IIC ratings, it may be necessary to isolate the ceiling from the floor above. This can be accomplished by suspending the ceiling with resilient channels or isolation hangers. Good architectural practices, including careful isolation design and attention to detail in construction, are important to ensure the realization of high IIC ratings. References D8 and D11 to D15 in the bibliography provide extensive IIC test data. Product manufacturers can be consulted for additional data.

D2.5.2 Design guideline for noise isolation from vibrating machinery. Vibration isolation methods, such as rubber pads or spring systems under the mounting points, should always be employed under rotating machinery to isolate it from floor-ceiling systems and prevent structurally-transmitted sound from entering learning spaces. This isolation is particularly important for roof-mounted rotating machinery where the deflection of the roof has to be considered in vibration isolation design. Design methods for such vibration isolation are documented in widely available noise control handbooks, (See ref. D2, D8 and D15 in the bibliography).

Annex E (Normative)

"Good architectural practices" and procedures to verify conformance to this standard

E1 Introduction

This annex provides recommendations in clause E2 for "good architectural practices" that will help to achieve the objectives of this standard. Clauses E3, E4, and E5 describe procedures that shall be followed to verify conformance to the requirements and recommendations of this standard, in the event that such verification is required. If verification of conformance is not required, the procedures described in clauses E3, E4, and E5 are provided for information only and the entire annex then shall be considered to be informative rather than normative.

This standard covers a range of requirements, some of which are relatively simple to accommo-

date by following the design guidelines given in other annexes. However, concerns about the actual acoustical environment of learning spaces may arise depending on a combination of factors such as building siting, variability in the installation of the HVAC system, and variability in the details of the construction techniques. For these and other reasons, verification tests may be necessary to evaluate conformance to the requirements of this standard.

Nonconformance to the provisions of this standard may be suspected when subjective evaluation of a learning space under typical use indicates excessive background noise, reverberation, insufficient noise isolation, or poor speech intelligibility.

Verification tests and analyses, if required, should be performed by qualified personnel (see B6 in annex B).

E2 "Good architectural practices" and acoustical performance considerations during and after construction

E2.1 Prior to completing construction

"Good architectural practices" during the design and construction of a new or renovated learning space include the following actions:

phase 1 – designing to conform to this standard (see annexes B, C, and D);

phase 2 – monitoring activities during construction to ensure that acoustically important design features are not compromised; and

phase 3 – checking for conformance to the principal requirements of this standard before completion of construction or renovation is accepted.

For a new or a renovated learning space, the architectural design in phase 1 should utilize the guidance provided in annexes B, C, and D. Because many structural component assemblies involve work by more than one building trade, the architect's specifications should cross-reference the noise control and noise isolation measures in all applicable sections of the specifications.

During construction phase 2, in addition to, and in advance of, conventional on-site inspections, special training should be provided to those in relevant building trades who will perform the work, or to their supervisors. The training should describe guidelines for implementing what often may be unconventional or unfamiliar construction methods. For example, representatives of certain building trades may not realize that inadvertent or careless disposal of debris or temporary bracing in the space between wall surfaces can cause a drastic reduction in noise isolation between adjacent learning spaces.

It is important to emphasize to those doing the work during the construction phase that all cracks or joints between wall segments or wall-floor or wall-ceiling joints should be sealed with a permanently flexible caulking compound. However, no attempt should be made to seal cracks or joints that are wider than 6 mm (0.25 in.). Solid filler, also caulked, with a surface weight density comparable to that of the material on each side of the crack should be used to seal cracks that are wider than

6 mm. ASTM C919 [E1] provides procedures for the use of sealants to maintain the design for noise isolation. The architectural design drawings should include a reference to ASTM C919 for sealing procedures.

To check conformance to the key requirements of this standard after construction is completed but before the learning space is occupied (phase 3), the following evaluations are recommended:

- 1) measure the background noise levels within learning spaces,
- 2) measure the noise isolation between them, and
- 3) calculate (or measure) reverberation times (see E3, E4, and E5 for procedures).

E2.2 After commissioning

After commissioning (accepting completion of construction), "good architectural practices" include:

- 1) being alert for, and monitoring of, degradation of acoustical materials, and
- 2) responding to complaints about the acoustical environment in a learning space.

Over time, some of the noise control features designed into a learning facility may degrade. One example of such degradation is changes in the balance, or fan operation, of the HVAC system leading to excessive low-frequency noise. Another example is the degradation of designed noise isolation provided by operable partitions as a result of wear and tear of floor and edge seals. A third example is painting of the sound-absorbing material on ceilings and walls.

Tests to verify conformance to this standard may be performed in response to complaints about the acoustical environment in the learning spaces. The results of these tests, and those performed prior to accepting completion of construction, will assist in analyzing the basis for any future complaints about the acoustical environment in the learning spaces.

E3 Verifying background noise levels

E3.1 Selecting learning space for measurements

Ordinarily, comprehensive testing is not required for all learning spaces in a given facility to which this standard applies and appropriate sampling procedures should be adequate. Selection of the size of the sample should consider the need to

evaluate spaces expected to have the highest levels of background noise because of their proximity to internal noise sources (e.g., mechanical equipment rooms) or their proximity to external noise sources (e.g., road traffic).

The test procedures in the balance of this clause apply to each learning space in which background noise levels are to be measured.

E3.2 Room conditions

Background noise levels shall be measured while adjacent spaces (for example, rooms and corridors beside, above, and below the space in which the measurements are to be made) are unoccupied. Students or school staff members, in the remainder of the facility, shall be requested to not carry out any activity that could increase the background noise level in the room under investigation.

Background noise levels shall be measured during an hour when the background noise levels are expected to be a maximum. Background noise levels shall be measured with the HVAC system and other building services at their appropriate maximum operational conditions as specified in 4.3.2. Lights shall be on; doors and windows shall be closed.

E3.2.1 Instructional equipment

Portable and permanent instructional equipment (for example, computers and audio-visual systems) shall be turned off to obtain background noise levels required by this standard.

However, it is strongly recommended that background noise levels also be measured according to the procedures in this annex when such instructional equipment and building services are operating simultaneously. When this total background noise level exceeds the limit in table 1 by more than 3 dB, steps should be taken to reduce the level of the noise produced by the instructional equipment.

E3.3 Room description

The overall dimensions of the learning space shall be measured and the enclosing volume calculated. The locations and dimensions of major features shall be noted on a diagram with plan and elevation views showing: 1) the location of HVAC components and other noise sources within the

space; 2) the position and dimensions of windows and doors; and 3) the heights and locations of partial height walls.

E3.4 Test instruments

Two types of instruments are required — a sound level meter and a compatible acoustical calibrator (or sound calibrator).

E3.4.1 Sound level meter. The sound level meter shall provide frequency weightings A and C, and SLOW time-weighting.

The sound level meter shall be an integrating-averaging type capable of measuring time-average sound levels or a conventional sound level meter capable of measuring SLOW time-weighted sound levels. An integrating-averaging meter is preferred.

An integrating-averaging sound level meter shall conform to the class 1-performance specifications of IEC 61672-1 [E2] or to the performance specifications of ANSI S1.43 [E3] for type 1 integrating-averaging sound level meters. A conventional sound level meter shall conform to the class 1 specifications of IEC 61672-1 or to the specifications of ANSI S1.4 [E4] for type 1 sound level meters. For either type of sound level meter, conformance to IEC 61672-1 is preferred.

To demonstrate conformance to the background noise limits of table 1, the maximum A-weighted level of self-generated noise of the sound level meter shall not exceed 30 dB for the model of microphone installed on the sound level meter.

NOTE Sound level meters designed in conformance with the above IEC or ANSI standards may have A-weighted self-noise levels greater than 30 dB. Conformance to these standards does not assure compliance with this required maximum self-noise level.

To carry out the preliminary survey of the background noise levels in the manner described in E3.7, a conventional sound level meter conforming to IEC 61672-1 class-2 or ANSI S1.4 type-2 specifications may be an acceptable alternative. To be acceptable, the lowest noise level measurable by the instrument shall be at least 5 dB below the actual measured background level. This ability may be demonstrated by observation in a very quiet location. Alternatively, the manufacturer may provide the lowest measurable level for this instrument.

E3.4.2 Acoustical calibrator. The acoustical calibrator shall conform to the requirements of IEC

60942 [E5] for a class 1 instrument or to the requirements of ANSI S1.40 [E6] for a type 1 instrument. Conformance to the standard corresponding to the sound level meter standard is preferred. The actual sound pressure level and nominal frequency of the calibration signal shall be known for the microphone installed on the sound level meter.

E3.5 Calibration

The sound level meter and the acoustical calibrator shall each have a certificate from a qualified acoustical testing laboratory indicating that a calibration of both instruments has been performed within the time interval recommended by the manufacturer but not more than 24 months prior to the date of the tests. The certificate shall apply for reference environmental conditions defined by the manufacturer. The calibration of the sound level meter and acoustical calibrator shall be checked periodically to ensure that measurements with the sound level meter are accurate.

Before initiating sound level measurements, the calibration of the sound level meter shall be verified in accordance with the procedure described in the Instruction Manual for the calibrator. Adjustments shall be made to the calibration in accordance with this manual to account for any significant difference between the prevailing atmospheric pressure and air temperature and the reference conditions (i.e. - 760 mm Hg, and 23 °C).

E3.6 Selecting measurement locations

The customary listening areas used for speech communication shall be determined for each learning space. The customary listening areas include the students' seating areas and the areas used by the teacher. These listening areas may be relatively fixed within a classroom or vary substantially, depending on the seating arrangement and teaching style. A maximum of six measurement locations shall be selected within the customary listening area and at distances not less than 1 m (40 in.) from a wall or other large solid surface, except for measurement locations close to the floor.

The location in the customary listening area that has the highest sound level shall be designated the "key location". This location shall be determined by observing the A-frequency-weighted and SLOW time-weighted sound level as the sound level meter is carried around the learning space with the room conditions as noted in E3.2. Sound

levels shall be noted at measurement heights representative of seated and standing students. Alternatively, this key location may be selected by listening at suitable positions near the apparent source of highest noise levels. If this subjective choice of the key location cannot be confirmed by the subsequent measurements of background noise, the background noise measurements shall be repeated using a correct key location. Before determining the other measurement locations it is prudent to evaluate preliminary survey results at the key location, as called for in E3.7.

A second location shall be on the opposite side of the listening area from the key location. Four other locations, two on each side of the listening area, shall be selected ahead and behind the key and second locations.

Three of the measurement heights above the floor, including that for the key location, shall be at the nominal ear elevation for students seated in a chair or on the floor. The other three heights shall be representative of the ear position of a standing student. The recommended approximate heights are shown in the following table.

Grade level	Approximate measurement height above the floor		
	Seated positions		Standing
	In a chair	On the floor	
K to 6	0.8 m (33 in.)	0.5 m (20 in.)	1.1 m (44 in.)
7 to 9	1.0 m (40 in.)	Not applicable	1.4 m (54 in.)
10 to 12 and adults	1.1 m (44 in.)	Not applicable	1.5 m (60 in.)

For learning spaces used by students of widely varying ages, at least four of the six measurement locations shall be those for the younger students.

Each measurement location shall be shown on a floor plan diagram and shall include the actual measurement heights employed.

E3.7 Measuring background noise

Following the initial survey described below, which can employ a hand-held sound level meter, the remainder of the background noise measurements should be conducted with the meter mounted on a tripod to minimize operator-induced noise and reflections from the operator's body. (A tripod may be

necessary for even the initial survey if the observed sound levels are very low). A large flat surface, such as a table or chair seat, shall not be used to support the instrument. To ensure that any air currents do not affect the reading of the sound level meter, and to protect the microphone from accidental damage, an appropriate microphone windscreen shall always be employed. The number of persons in the listening area shall be minimized, preferably with the test conductor the only person in the area.

The measurement of background noise shall begin with a preliminary survey to:

- 1) find the key location where the background noise level is the highest (see E3.6);
- 2) assess the likelihood that the background noise level conforms to the limits in table 1; and
- 3) determine if the background noise is steady or unsteady.

The sound level meter used for this preliminary survey may be an integrating-averaging type or a conventional type. In either case, it may be one that conforms only to the class-2 requirements of IEC 61672-1 or the type 2 requirements of ANSI S1.4 if the meter also conforms to the requirements in E3.4.1 for the lowest measurable level.

At the key location, the time-average A-weighted sound level shall be measured over each of five nominally consecutive 30-second intervals. The highest 30-second average, the lowest 30-second average and the total average of all five 30-second averages shall be noted. The same type of data shall be obtained for C-weighted sound levels. Each 30-second average may be obtained with an integrating-averaging meter set to a 30-second averaging period or, with a conventional sound meter, by visually observing the mean indication of the A-weighted and SLOW time-weighted sound level over the 30-second interval.

If the average background noise level from the above five A-weighted measurements is at least 3 dB more than the limits in table 1, then it may be concluded that the background noise levels in the room are not in conformance with the standard. No further background noise measurements are needed. If the average background noise level from the above five measurements is at least 3 dB less than the limits in table 1 and the background noise is judged steady as defined below, it may be concluded that the background noise levels in the room are in conformance with the standard. No

further A-weighted background noise measurements are needed.

If the average of the five 30-second samples falls within a 3 dB range above or below the limits of table 1, then confirmation of conformance or non-conformance to these limits shall be determined by additional tests carried out in accordance with one of the following procedures.

If the difference between the highest and the lowest noise levels of the five 30-second samples at the key location is not more than 3 dB, the background noise shall be judged steady and the measurement procedure in E3.7.1 shall be employed. If this difference is more than 3 dB, the background noise shall be judged unsteady and the measurement procedure of E3.7.2 shall be employed.

E3.7.1 Steady background noise. The one-hour-average steady background level for the typical usage hour may be obtained from measurements of one 30-second average sound level at each measurement location after ensuring that the room conditions are as specified in E3.2. Each 30-second average sound level may be measured in one of two ways and the results noted for each measurement location:

- 1) by use of an integrating-averaging sound level meter for a 30-second measurement interval or
- 2) by visual observation for 30 seconds of the mean sound level observed on a conventional sound level meter with SLOW time-weighting.

If any non-typical short-duration sound, such as a door slam, occurs during any measurement period, the measurement shall be stopped, the memory cleared if an integrating-averaging instrument is being used, and the 30-second measurement repeated.

The C-weighted sound level also shall be measured at the key measurement location applying the same process employed for the A-weighted sound levels. If the C-weighted sound level at this location exceeds the limit for A-weighted levels in table 1 by more than 18 dB, it is recommended that a more thorough evaluation be made of the C-weighted levels at other locations in the room to ensure conformance to 4.3.2.1.

E3.7.2 Unsteady background noise from transportation noise sources. For unsteady background noise, the measurement procedure of E3.7.1 (1) shall be followed, using an integrating-averaging sound level meter which, preferably,

can also determine the A-weighted SLOW time-weighted noise level exceeded for 10% of any measurement interval. The integration and averaging measurement interval shall be 60 minutes instead of 30 seconds.

During this measurement, the time of day and the apparent sources of significant transportation noise shall be identified and noted. Non-typical short-duration loud sounds that occur during the integration interval shall be noted, but the integration shall not be interrupted. Prior to reporting the one-hour-average sound level, the measured data may be processed to exclude such non-typical short-duration sounds.

The A-weighted, SLOW time-weighted noise level exceeded for 10% of the observation hour shall be noted directly if the sound level meter has this capability. Alternatively, manual data processing may be employed. For example, a record of 120 observations of 30-second samples of the A-weighted SLOW time-weighted noise level can be used to determine the level exceeded for 10% of the hour.

E3.7.3 Disturbing sounds from building services and utilities. If the presence of disturbing sounds (see 4.3.2.2) is suspected from building services and other utilities, a more thorough analysis of the acoustic environment may be required using appropriate signal analysis equipment familiar to an experienced observer.

E3.8 Verifying conformance to background noise limits

E3.8.1 Steady background noise. For the customary listening area in the learning space, conformance to the requirements of this standard is verified for steady background noise when the following conditions are satisfied.

- The 30-second-average A-weighted sound level at each measurement location does not exceed the corresponding limit specified in table 1, within the tolerance of 4.7 (1); and
- The 30-second-average C-weighted sound level at the key measurement location does not exceed the corresponding 30-second-average A-weighted sound level by more than the limit specified in 4.3.2.1.

E3.8.2 Unsteady background noise from transportation noise sources. Conformance is verified if the one-hour-average A-weighted sound level and the A-weighted, SLOW time-weighted

level exceeded 10% of the time do not exceed the limits specified in 4.3.1. The tolerance of 4.7 (1) applies separately and not cumulatively to each of these limits for the continuous test hour.

E4 Verifying reverberation times

E4.1 Methods

The preferred method to verify that the actual reverberation times do not exceed the maximum reverberation time specified in table 1 is to calculate the reverberation time at 500 Hz, 1000 Hz, and 2000 Hz. Alternatively, reverberation times may be measured directly. Reverberation times shall be measured when the calculated reverberation times exceed the limits from table 1, when the observed reverberation of the learning space appears to be excessive, or when significant differences are suspected between the assumed and the actual mounting conditions for the acoustic treatment.

If calculated and measured reverberation times differ by more than 0.1 s, the measured reverberation time shall take precedence. Results of calculations or measurements of reverberation times shall be rounded to the nearest 0.1 s and shall be within the tolerance limits of 4.7 (4) of the performance requirements in table 1.

E4.2 Reverberation time by calculation

The dimensions of the room shall be measured and the enclosing volume calculated. The dimensions of the sound-absorbing surfaces on the ceiling and walls shall be measured and the surface areas calculated for each different type of sound-absorbing surface.

The total sound-absorbing area in the room shall be determined by means of equation (C.2) in annex C with appropriate estimates for the sound absorption coefficients for the various sound-absorbing surfaces. A residual sound-absorbing area shall be computed according to C2.1 in annex C to account for absorption by furnishings and untreated surfaces. A default value for this residual absorption shall be 15% of the floor area for uncarpeted rooms or 20% for carpeted rooms. Sound absorption provided by occupants of the room shall be ignored. The reverberation time shall be calculated for each frequency by the Sabine equation (e.g. - see equation (C.1) in annex C).

E4.2.1 Sound absorption coefficients used for calculations. To calculate the reverberation time, best estimates of the sound absorption coefficients for the as-installed acoustic materials shall be used. These coefficients (see NOTE) shall be obtained from:

- a) the acoustical materials contractor, accompanied by the certification that they were obtained in accordance with ASTM C423 (see C2.1 in annex C) or,
- b) published results obtained in accordance with ASTM C423 for nominally identical materials and mounting configurations, (see bibliography)

If possible, allowance should be made for acoustically significant differences between the tested and as-installed mounting configuration.

NOTE Manufacturers do not commonly provide the octave band sound absorption coefficients needed for this standard. The values reported are usually those measured for one-third octave bands centered at these octave frequencies. If desired, sound absorption coefficients over the full octave band may be estimated by arithmetically averaging available one-third octave band values at 400, 500, and 630 Hz for the 500 Hz octave band, at 800, 1000 and 1250 Hz for the 1000 Hz octave band, and at 1650, 2000, and 2500 Hz for the 2000 Hz octave band.

When such reasonable data or estimates of the sound absorption coefficients are not available then verification of reverberation time shall only be done using the measurement method in E4.3.

E4.3 Reverberation time by measurement

Measurements of reverberation times shall be performed by, or under the supervision of, a person experienced in performing such measurements. The measurements shall follow procedures in conformance with, or equivalent to, those specified for field tests in ASTM E336 [E7] or in Appendix X2 of ASTM C423 [E8]. The recommended sound signal is random noise with a bandwidth extending at least from 315 Hz to 3150 Hz.

Reverberation times shall be measured at least at the key location noted in E3.6 for each learning space where reverberation times are to be measured.

Before measuring reverberation times, all HVAC fans and other noise-generating equipment, such as instructional equipment, should be turned off if

their noise prevents acquisition of valid measurements of reverberation times. All soft materials that are not a permanent part of the learning space (such as loose clothing and art supplies) shall be removed from the room. The learning space shall be otherwise furnished in the normal manner with chairs, tables, shelves, or cabinets. All windows, doors, and cabinets shall be closed. No more than two persons shall be present during the actual measurements.

No adjustments shall be made to any reverberation time measurements to account for the added absorption of any furnishings of any sort that were not present in the room at the time of the measurements.

E5 Verifying airborne and structureborne noise isolation

E5.1 Airborne noise isolation

When required, tests for conformance to airborne noise isolation requirements in table 2 shall be performed in accordance with the procedures of ASTM E336 [E7] and ASTM E413 [E9] for determining the Noise Isolation Class (NIC) as an approximation to the sound transmission class (STC) rating of a structural element. If there are no significant flanking sound-transmission paths and all sound leaks have been well sealed, the NIC rating is usually equal to, or slightly greater than, the STC rating determined by field tests for assemblies that separate two enclosed learning spaces.

The same ASTM test procedures also should be used to demonstrate conformance with the STC ratings recommended in table 3 for receiving ancillary learning spaces. All sound transmitted from the source room to the receiving room shall be considered to be transmitted through the separating partition. Engineering judgment shall be applied in the interpretation of measured NIC ratings; guidance for this judgment is provided in ASTM E336. The measured NIC ratings shall be within the tolerance limits of 4.7 (2) of the STC design requirements in table 2 and design recommendations in table 3.

E5.2 Structureborne (impact) noise isolation

When required, tests for conformance to structureborne or impact noise isolation requirements in 4.5.6 shall be performed in accordance with the testing procedures for determination of the Field Impact Insulation Class (FIIC) as defined in ASTM

E1007 [E10] for floor-ceiling assemblies separating occupied spaces from learning spaces below. All sound transmitted from the source room to the receiving room below shall be considered to be transmitted through the floor-ceiling assemblies.

E5.3 Sound leakage paths

Tests for airborne and structureborne noise isolation shall not be attempted until all sound leakage paths and gaps have been eliminated by caulking and sealing in accordance with the recommended practice in ASTM C919 [E1].

E6 Test report

A test report shall document the results of all tests or calculations carried out in conformance with the procedures of E3 to E5 of this annex. The report shall reference this standard and the applicable clauses of this annex. The report shall describe the instruments used and their dates of calibration when applicable. The report shall include tables of all measured data and the results of all analyses. Drawings shall be included to show the items noted in E3.3 and E3.6. To support validation of the reverberation time by calculations, the report shall also include the types, locations, and areas of permanently installed sound-absorbing material and their mounting methods.

The report shall state whether the learning space does or does not conform to the requirements of this standard and shall identify the applicable clause(s). If the space does not conform to the requirements of this standard, the report may include, if requested, recommendations for modifications to achieve compliance. These recommendations should be prepared or approved by a person experienced in the applicable acoustical technology.

The report shall name the persons performing the validation tests or calculations and the name of the person who prepared the report.

Annex F (Informative)

Potential conflicts between the acoustical requirements of this standard and indoor air quality (IAQ) and multiple chemical sensitivity (MCS)

F1 Introduction

Concerns about indoor air quality (IAQ) and multiple chemical sensitivity (MCS) issues have

caused some schools to remove all porous materials from the classrooms and, in some cases, from the ventilation supply ducts, thus potentially compromising the benefits for classrooms that used

these acoustical materials. However, according to available literature and other sources such as those listed below, there is little or no conflict between the applications of this standard for classroom acoustics and IAQ and MCS issues when the proper materials are used and properly maintained. Nevertheless, the concerns need to be addressed. This annex provides a bibliography of references from government organizations, industry associations, and other organizations that offer relevant information.

Educational facility planners and architectural designers should objectively investigate any questions and concerns about IAQ and MCS issues that they may have relative to the acoustical design concepts presented in this standard.

Many materials employed to provide the desired acoustical environments by means of effective noise control are porous or fibrous in nature. Therefore, certain considerations such as material composition, potential out-gassing, and appropriate operating and maintenance strategies need to be addressed in the decision-making process relative to the types of materials proposed for acoustical purposes.

If acoustical materials are considered to be inappropriate under certain conditions, alternative materials, strategies, or applications should be employed to ensure conformance to the acoustical requirements of this standard.

In some cases a management commitment will need to be made to ensure that materials selected and used in a facility will be maintained in an appropriate manner, as recommended by the manufacturer or other governing bodies, under operational conditions after construction of the facility. For example, in hot and humid climates a facility should be adequately ventilated or other recommended measures should be taken at all times to ensure prevention strategies involving the potential for mold growth.

To reduce the potential for mold growth in HVAC systems, good design, installation and maintenance practices should be employed in order to keep filters and sound-attenuating materials clean and dry. This practice should include cleaning and periodically replacing or discarding tennis ball halves that are frequently used on chair legs to minimize shuffling noise. Limited tests have shown that these tennis ball halves develop an active fungal growth. The alternative method for quieting shuffling noise with neoprene chair leg tips should be encouraged.

Annex G (Informative)

Cautionary remarks on using supplemental descriptors for evaluating noise in classrooms and other learning spaces

G1 Introduction

There are at least three noise descriptors, other than A-weighted sound levels, that are used to as-

sess background noise or speech intelligibility in enclosed spaces, especially when low-frequency content is a major concern. However, applying the descriptors discussed below requires determining

the frequency spectrum of the noise – a refinement that is beyond the scope of this standard and is not recommended.

A-weighted and C-weighted sound levels are considered adequate descriptors for purposes of this standard to evaluate the acoustical environment in learning spaces. The difference, measured in 56 classrooms, between the A-weighted time-average sound level of steady background noise and the corresponding value of any of the three descriptors noted below varied from 2 dB to 24 dB depending on the location of the learning space in the U.S. and whether the HVAC system was operating. *Thus, none of these supplemental descriptors should be employed for judging conformance to this standard.*

G2 Noise Criteria Rating (NC)

The noise criteria (NC) rating, in common use by architects and consultants for acoustical room design, is based on contours of octave-band sound pressure levels of the background noise. It is thus a measure of the frequency spectrum of this noise and reflects the change in the sensitivity of human hearing as the background noise level changes [G1], especially at frequencies important for speech communication and for annoyance of low-frequency sound.

G3 Balanced Noise Criteria Rating (NCB)

The balanced noise criteria (NCB) rating [G2] are also based on similar contours of octave-band sound pressure levels. The contours for the NCB descriptor extend to lower frequencies than do the contours for the NC descriptor.

G4 Room Criteria Rating (RC)

The room criteria (RC) rating [G3] is recommended by ASHRAE for evaluating background noise from HVAC systems and other mechanical equipment by use of contours of octave-band sound pressure levels. These contours are similar to those for the NC and NCB descriptors but have lower allowable sound levels at very low and very high frequencies.

Please visit the ASA Home Page at <http://asa.aip.org> for the latest information, including updates, on the national and international standards distributed by the Acoustical Society of America.

**STANDARDS SECRETARIAT
ACOUSTICAL SOCIETY OF AMERICA**

The Standards Publication Program of the Acoustical Society of America (ASA) is the responsibility of the ASA Committee on Standards (ASACOS) and the ASA Standards Secretariat, headed by its Standards Manager.

The Acoustical Society of America provides the Secretariat for four Accredited Standards Committees of the American National Standards Institute (ANSI): S1 on Acoustics, S2 on Mechanical Vibration and Shock, S3 on Bioacoustics, and S12 on Noise.

These four Accredited Standards Committees also provide the United States input to various international committees (IEC and ISO). Standards Committees S1 Acoustics and S3 Bioacoustics provide the United States input to ISO/TC 43 Acoustics, and IEC/TC 29 Electroacoustics, as the Technical Advisory Groups. S12 on Noise serves as the U.S. Technical Advisory Group for ISO/TC 43/SC1 Noise. S3 is the U.S. Technical Advisory Group for ISO/TC 108/SC4 Human Exposure to Mechanical Vibration and Shock. S2 serves as the U.S. Technical Advisory Group for ISO/TC 108, Mechanical Vibration and Shock; ISO/TC 108/SC1, Balancing, including Balancing Machines, ISO/TC 108/SC2 Measurement and Evaluation of Mechanical Vibration and Shock as Applied to Machines, Vehicles, and Structures; ISO/TC 108/SC3 Use and Calibration of Vibration and Shock Measuring Instruments; ISO/TC 108/SC5 Condition Monitoring and Diagnostics of Machines; and ISO/TC 108/SC6 Vibration and Shock Generating Systems.

ASACOS and the ASA Standards Secretariat provide the Secretariat for the U.S. Technical Advisory Groups listed above and administer the International Secretariat for ISO/TC 108 Mechanical Vibration and Shock, ISO/TC 108/SC1 Balancing, Including Balancing Machines, and ISO/TC 108/SC5 Condition Monitoring and Diagnostics of Machines.

Standards are produced in four broad areas: physical acoustics, mechanical vibration and shock, bioacoustics, and noise, and are reaffirmed or revised every five years. The latest information on current ANSI standards (including Nationally Adopted International Standards (NAIS Standards)), as well as those under preparation is available from the ASA Standards Secretariat. For information, please contact S. B. Blaeser, Standards Manager, Acoustical Society of America, 35 Pinelawn Road, Suite 114E Melville, NY 11747, USA. E-mail asastds@aip.org. Nonauditory Effects of Noise on Children: A Critical Review

Gary W. Evans
Cornell University
New York, USA

Stephen J. Lepore
Carnegie Mellon University
USA

Large numbers of children both in the United States and throughout the economically developing world are chronically exposed to high levels of ambient noise. Although a great deal is known about chronic noise exposures and hearing damage, much less is known about the nonauditory effects of chronic ambient noise exposure on children. To estimate the risk of ambient noise exposure to healthy human development, more information about and attention to nonauditory effects such as psychophysiological functioning, motivation, and cognitive processes is needed. This article critically reviews existing research on the nonauditory effects of noise on children; develops several preliminary models of how noise may adversely affect children; and advocates an ecological perspective for a future research agenda.

Keywords: noise, stress, nonauditory effects, health, cognitive

INTRODUCTION

In 1973 nearly 10 million American school children were exposed to ambient noise levels that exceed federal standards for hearing protection in work settings (Environmental Protection Agency, 1974). Recent studies estimate that American children on average are exposed daily to noise levels in the range of 76-80 Leq (unweighted average of decibel levels for 24 hours) (Roche et al., 1982; Schori & McGatha, 1978). To put these figures in perspective, the EPA recommended limit for risk to hearing is 70 Leq daily exposure for children. Since these assessments of childhood noise exposure, there have been marked increases worldwide in the number of children exposed to noise levels loud enough to impair hearing; this is especially true in underdeveloped countries (Evans, 1990; Suter, 1991).

Many *nonauditory* effects of noise on children also have been detected during the past two decades of research. Nonauditory effects of noise refer to impacts not directly related to sound-

induced damage to the auditory system. Non-auditory effects of noise, such as elevated sympathetic nervous system activity or disturbances in attentional processes, are apparent in children exposed to noise levels far below those necessary to induce auditory damage.

Although there is abundant evidence and analysis of the auditory effects of noise on children (Kryter, 1985; Mills, 1975), there has been little systematic, critical analysis of the nonauditory effects of noise exposure among children. This is a critical omission if we are interested in estimating the true risk of noise exposure to healthy human development. The present article critically examines the empirical evidence on the nonauditory effects of noise on children. The work is organized into three general areas of functioning: physiological, motivation, and cognitive. Both conceptual as well as methodological limitations in the extant research are examined.

Physiological Effects of Noise

Work in animal models and in various occupational settings suggests heightened activation of the cardiovascular system among organisms

Table 1. Effects of noise on cardiovascular outcomes

Author(s)	Outcome	Noise Source/Level	Sample Population (n)	Basic Result
Chronic noise				
Brackbill et al. (1982)	HR	1 h white noise for 4 consecutive days. 50 and 75 dBA.	(78 males) ages 1 mon. to 80 yrs.	In infants and 8-year olds, HR decreased as sound levels increased. No other main or interactive effects of noise.
Cohen et al. (1980)	BP	Aircraft. 95 dBA peak.	(262) grades 3-4.	Noisy-school children had higher SBP and DBP than quiet-school children.
Cohen et al. (1981)	BP	Aircraft. 95 dBA peak.	(163) grades 3-4, longitudinal sample.	In the longitudinal attrition sample, there were no effects of noise on BP.
Cohen et al. (1985)	BP	Aircraft. 16 dBA sound reduction in noise-abated classrooms.	(163) grades 3-4, longitudinal sample.	SBP marginally lower and DBP significantly lower in quiet- than noisy-school children. SBP and DBP marginally lower in quiet- than noise-abated school children. No BP differences in children in noisy vs. noise-abated school.
Cohen et al. (1986)	BP	Aircraft. 95 dBA peak.	(165) grade 3, new sample.	Noisy-school children had higher BP than quiet-school children if were enrolled for 2 yrs or less. No noise effects on children enrolled more than 2 yrs.
Karsdorf & Klappach (1968)	BP	Traffic and street. 63-84 phon.	(262) grades 7-10.	Children in quiet schools had normal BP; whereas those in moderately- to very-noisy schools had elevated BP, especially among older boys.
Ising et al. (1990)	BP	Low altitude military flights. 125 dBA peak/Leq 68 dBA.	(433) ages 10-13 yrs.	Noise-related increases in SBP and DBP for girls, but not boys. Noise-related HR deceleration in boys and girls, but deceleration only significant in boys.
Karagodina (1969)	BP	Aircraft. 112 dBA peak/Leq 58 dBA.	(unavailable) ages 9-13 yrs.	Noisy-school children had higher BP than quiet-school children.
Roche et al. (1982)	BP	Self-report of exposure to loud noise sources. 80-Leq.	(233) ages 12-14 yrs.	Self-reported noise exposure levels not associated with BP.

Note: HR = heart rate, BP = blood pressure, S = systolic, D = diastolic.

chronically exposed to noise (Kryter, 1985; Smith, in press). As shown in Table 1, several studies have also uncovered evidence of possible linkages between chronic noise exposure and elevated blood pressure among children.

With two exceptions, all of the studies shown in Table 1 report elevations of resting blood pressure among children chronically exposed to noise. The one experimental study (Brackbill et al., 1982) found habituation to noise, which is a well established psychophysiological finding with short-term noise exposures (Glass & Singer, 1972). The extent of blood pressure elevations found from chronic exposure are probably not clinically significant for children during their youth (Voors et al., 1976), but could portend elevations later in life that might be health damaging (Berenson, 1980). To our knowledge,

there have been no long-term follow up studies of children exposed to noise at an early developmental stage. We know essentially nothing about the long-term consequences of early noise exposure on developing cardiovascular systems.

Both of the studies in Table 1 that found nonsignificant correlations between noise exposure and chronic blood pressure levels have methodological limitations. Roche et al. (1982) relied on children's retrospective reports of exposure to noise events (e.g., motorcycle use) during the previous six months. No data were presented on the reliability or validity of these noise estimates. Furthermore, the children monitored did not live near especially high noise sources (e.g., airports). Instead exposure to point noise sources such as machinery was estimated. Finally, resting blood pressure was only estimated

with one reading. On the other hand, this is the only study to examine the association between typical, daily noise exposures and resting blood pressure among children. All other studies have assessed the association between chronic blood pressure and exposure to high noise sources such as airports, roads, or trains. Analyses of the health effects of typical noise exposure for children are needed but with more adequate measurements of both noise exposure and blood pressure.

The second study to find a nonsignificant association between chronic noise exposure and resting blood pressure levels was conducted with children exposed to high levels of noise from an airport. Cohen et al. (1981) found that a difference in blood pressure between children attending noisy versus quiet elementary schools in a cross-sectional analysis did not replicate when reassessed one year later. Attritional analyses suggested that the failed longitudinal replication was caused by emigration of the families of children in noisy areas with the highest levels of blood pressure. Among children attending quiet schools, on the other hand, there was no selective attrition related to blood pressure levels.

Unlike other studies listed in Table 1, the three studies by Cohen and colleagues (Cohen et al., 1980; 1981; 1986) include statistical controls (e.g., social class, education) to counter potential third variable explanations of the associations uncovered between noise exposure and chronic levels of blood pressure. However, none of the studies is prospective, nor do any show a dose response relation between noise and blood pressure. Furthermore, all of the extant studies have relied upon gross indices of noise exposure - typically peak readings measured at schools.

Noise in the fetal and neonatal environment may be particularly harmful to fetuses and newborns because they are in a period of great organismic plasticity. It is well established that environmental sounds and vibration influence physiological and behavioral responses in the fetus (Pikus, 1991). There are contradictory data on the relations between ambient noise exposure and birth weight (for reviews see Pikus, 1991; Smith, in press) but little or no definitive evidence for teratological effects of chronic noise exposure (Edmonds et al., 1979; Meyer et al., 1989). Nonetheless, it is critical for more thorough and extended investigation of the potential impacts of routine modern medical procedures such as ultrasound monitoring or

placement of premature babies in intensive care nurseries with extremely noisy equipment (Gottfried et al., 1981; Lawson et al., 1977).

Summary

Residing or attending school near a major noise source is associated with elevated blood pressure. More research is clearly called for, especially tracking children before, during, and after exposure to noisy environments. All evidence to date is correlational and even though some studies have included good controls, stronger, quasi-experimental designs are needed to firmly tie noise to the etiology of cardiovascular changes in children. The degree of blood pressure elevations is small, on the order of 4-8 mm of mercury, but these elevations do not appear to habituate with continued exposure (cf., Cohen et al., 1986). The clinical significance of such changes in childhood blood pressure is difficult to determine. The ranges of blood pressure among noise-exposed children are within normal levels and do not suggest hypertension. On the other hand, elevations in blood pressure among children appear to track into adulthood (Beren-son, 1980), increasing the potential risk for cardiovascular disease. It would also be of value to examine neuroendocrine makers of stress (e.g., cortisol) that have been implicated in the casual pathways between stressors and cardiovascular outcomes.

Emotional/Motivational Effects of Noise

The uncontrollability of chronic noise exposure may affect children's emotional and motivational states. When organisms are exposed to repeated, uncontrollable events, learned helplessness can occur (Abramson et al., 1978; Seligman, 1975). Learned helplessness means the organism learns that the outcomes of its behavior are independent of its responses. Learned helplessness is manifested as a lack of effort or responsiveness to environmental stimuli and challenges. Uncontrollable noise has been shown to induce helplessness in adults (Hiroto, 1974; Hiroto & Seligman, 1975; Krantz et al., 1974). Moreover, adults immediately following exposure to uncontrollable noise are less likely to persist on difficult or challenging aftereffect puzzles than their counterparts with prior exposure to controllable noise (Cohen, 1980; Glass & Singer, 1972).

Overall, though, very little is known about the

Table 2. Effects of noise on motivation (learned helplessness)

Author(s)	Outcome	Noise Source/Level	Sample Population (n)	Basic Result
Chronic noise				
Cohen et al. (1980)	Performance on moderately difficult puzzle after pretreatment with insoluble or soluble puzzle.	Aircraft. 95 dBA peak.	(262) grades 3-4.	Noisy-school children failed more on pretreatment soluble puzzle and difficult test puzzle, and were more likely to give up on difficult puzzle, than quiet-school children. There was a nonsignificant trend suggesting that longer exposure to a noisy school was associated with greater time to complete difficult puzzle.
Cohen et al. (1981)	Performance on moderately difficult puzzle.	Aircraft. 95 dBA peak.	(163) grades 3-4, longitudinal sample.	Noisy-school children were more likely to fail at the test puzzle and to take longer to solve the puzzle than quiet-school children. No noise effect on rate of giving up.
Cohen et al. (1981)	Performance on moderately difficult puzzle.	Aircraft. 16 dBA sound reduction in noise-abated classrooms.	(163) grades 3-4, longitudinal sample.	Sound attenuation improved children's performance on the original test puzzle.
Cohen et al. (1986)	Performance on moderately difficult puzzle.	Aircraft. 95 dBA peak.	(165) grade 3, new sample.	Noisy-school children failed difficult puzzle more frequently than did quiet-school children.
Cohen et al. (1986)	Choice task.	Aircraft. 95 dBA peak.	(165) grade 3, new sample.	Noisy-school children more likely than quiet-school children to give choice of reward to experimenter.
Moch-Sibony (1984)	Rosenzweig frustration tolerance test.	Aircraft. 29 vs 54 SIL.	(80) kindergarten.	Noise-related decreases in frustration tolerance.
Wachs (1987)	Observer ratings of mastery-oriented play behavior.	Ratings of noise: 1 = normal level voices in home for 15 min. period to 4 = noisy level voices in home for more than half 15 min. period.	(88) 12 mon.	Less mastery-oriented play behavior in noisier homes.

Note: SIL = speech interference level.

relations between chronic exposure to environmental stressors such as noise and the induction of helplessness in human beings. Community surveys of noise annoyance frequently note that while annoyance is common, complaints or other actions to intervene are rare (Evans & Tafalla, 1987). Most residents who are annoyed by noise report feeling unable or helpless to alter the situation (Jue et al., 1984). The small minority who do complain or take other actions report feeling greater self-efficacy to cope with the noise (Jue et al., 1984).

As shown in Table 2, a few studies have examined the effects of noise on children's motivational states. The significant relations between noise exposure and motivational deficits in one cross-sectional study (Cohen et al., 1980) were replicated both in a longitudinal study (Cohen et al., 1981) and in a second, cross-sectional study

(Cohen et al., 1986). Higher noise exposure in children has been associated with reduced persistence on challenging puzzles and greater abdication of choice over rewards (see Table 2). Perhaps the most persuasive data of reduced motivation in an achievement related situation is Cohen et al.'s (1980) findings on giving up. Not only were children from noisy schools less likely to solve a challenging puzzle within a four minute time period, a substantially greater proportion of them (15%) simply gave up before the allotted time had elapsed, often remarking that they couldn't do the task, in comparison to 2% of their quiet school counterparts who gave up.

Of additional interest, teachers from schools located in noisy settings report more difficulties motivating students to perform than do teachers from relatively quiet schools (Crook & Langdon, 1974; Kyzar, 1977; Moch-Sibony, 1984).

Even very young children appear to be less motivated to engage in object mastery or control over their environment, after prolonged exposure to noise. For example, 12-month-old infants living in noisier households tended to engage in less effective, mastery-oriented interactions with toys in their homes than did children from relatively quiet homes (Wachs, 1987).

Learned helplessness is more apt to occur when individuals make stable, personological attributions (e.g., ability) rather than ascribe global or temporary reasons (e.g., bad luck, poor effort) for their failures (Abramson et al., 1974; Silver et al., 1982). No research on noise and motivation has examined these underlying attributional processes. Future research should also directly manipulate contingencies in a task (e.g., provision of insoluble puzzles) and then examine differences in tendencies to become helpless along with attributional measures, as a function of chronic noise exposure. In addition, researchers should examine the possible mental health consequences of noise-related learned helplessness. If noise heightens vulnerability to helplessness, then it is reasonable to suspect possible connections between chronic noise exposure and certain psychological problems in children. In one exploratory study, Wachs (1988) found a positive association between noise levels in the home and adaptability, but noise was unrelated to several other indices of temperament. In another study, a composite index of noise and confusion/clutter in the home was linked to difficulty in care requirements for 18-month-old children, although not for 12-month or 24-month-olds (Wachs, 1989)

Summary

Brief exposures to uncontrollable noise are capable of inducing learned helplessness in adults. Chronic residential exposure to noise also appears to be associated with feelings of helplessness among adults living nearby airports. Although the evidence is scant, there are suggestive findings indicating that children chronically exposed to ambient noise sources may be more vulnerable to learned helplessness. Children attending schools in airport flight paths are less likely to solve or persist in attempting to solve challenging puzzles. They are also more likely to abdicate choice over a reward to an adult rather than exercising the choice option themselves. Teachers of children in noisy schools also report, on average, greater difficulties in

motivating children in their school work. Noise in the home may be associated with mastery motivation in very young children. In addition to the small number of studies, all of which are correlational, another drawback to this area of work has been a lack of systematic integration of more sophisticated developmental paradigms for the measurement of motivational deficits in children. The potential pathways among chronic noise exposure, helplessness, and psychological health warrant further research.

Cognitive Effects of Noise

Research on the cognitive effects of noise exposure on children has received the most attention from researchers. This area of research can be subdivided into three subtopics: (i) attention and perception, (ii) memory, and (iii) intellectual achievement.

Attention and perception

The cognitive ability to perceive order and contingency in the environment presumably depends on some modicum of sustained attention to event sequences as they unfold. The interruptive, distracting effects of high ambient noise levels might directly affect the young child's ability to sustain voluntary attention or to concentrate (Heft, 1985).

As shown in Table 3, studies by Karsdorf and Klappach (1968), Kyzar (1977) and by Moch-Sibony (1984) have revealed deficits in standardized measures of sustained attention among children chronically exposed to noise. The standardized tests involve searching for target geometric stimuli from among fields of similar objects. In addition, teachers report that children in noisy schools tend to have more difficulties in concentrating in comparison to children from relatively quieter schools (Crook & Langdon, 1974; Ko, 1979; Kryter, 1985; Kyzar, 1977).

Cognitive studies on children with variable exposures to chronic noise sources also indicate possible decrements in visual attention (see Table 3). Children from noisy homes took longer to locate target pictorial stimuli within an array of pictures than did children from relatively quiet homes (Heft, 1979). Children attending daycare centers located near train tracks performed marginally more poorly on a visual search task

Table 3. Effects of noise on attention

Author(s)	Outcome	Noise Source/Level	Sample Population (n)	Basic Result
Chronic noise				
Crook & Langdon (1971)	Teachers' reports of concentration.	Aircraft. 75 dBA peak.	(76 teachers) primary and secondary.	Teachers in noisy schools reported more concentration problems in students than did those in quieter schools.
Hambrick-Dixon (1986)	Cross-out letters in quiet or noise.	Train. 108 dBA peak.	(109 black) ages 4-6 yrs.	Children from noisy daycare performed task marginally worse than children from quiet daycare.
Hambrick-Dixon (1988)	Visual stimulus detection with verbal or key press response.	Train. 108 dBA peak.	(102 black) ages 5-7 yrs.	Interaction between location of daycare, response mode, exposure duration, and sex: On key response, girls in noisy daycare less than 2 yrs made more errors than girls in quieter daycare less than 2 yrs. On verbal response, girls in noisy daycare more than 2 yrs made more errors than girls in quiet daycare more than 2 yrs. No differences in performance of boys in any condition.
Heft (1979)	Response latency in visual search.	Noise ratings: 1 = low to 7 = high.	(94) ages 4-7 yrs.	Higher household-noise level associated with longer response latency.
Karsdorf & Klappach (1968)	Errors and latency on Bourbon test.	Traffic and street. 63-84 phon.	(262) grades 7-10.	Noisy-school students had longer response latency and more errors than quiet-school students.
Ko (1979)	Teachers' reports of concentration.	Aircraft. 105 dBA peak.	(2100 teachers) primary and secondary.	Teachers in noisy schools reported more concentration problems in students than did those in quieter schools.
Kyzar (1977)	Minnesota clerical test.	Traffic and street. 62-94 dBA.	(56) elementary school.	Noise-related deficits in clerical-type task.
Kryter (1985)	Teachers' reports of concentration.	Aircraft. 87 dBA peak.	unavailable.	Teachers in noisy schools reported more concentration problems in students than did those in quieter schools.
Moch-Sibony (1984)	Zazzo sustained attention task.	Aircraft. 29-54 SIL	(80) kindergarten.	Noisy-school children had poorer sustained attention than did quiet-school children.
Acute noise				
Zentall & Shaw (1980)	Visual search for letters.	Taped class noise from free time (71 dBA) and work time (57 dBA).	(36) grade 2 (hyperactive and non-hyperactive controls).	Noise × Hyperactivity interaction: Hyperactive children made fewer commission errors in low than in high noise conditions; non-hyperactive children unaffected by noise.

Note: SIL = speech interference level.

than did children from relatively quiet daycare centers (Hambrick-Dixon, 1986). In a subsequent study, Hambrick-Dixon (1988) uncovered a more complex relation between chronic noise exposure and attention, utilizing a vigilance task: Gender, exposure duration to train noise at the daycare center, and the response mode for the task (naming versus pressing a key) moderated the association between noise and performance.

Unfortunately, several of the sustained attention and noise studies suffer from methodological shortcomings. The Kyzar (1977) and Karsdorf and Klappach (1968) studies have inadequate controls

for sociodemographic factors. Furthermore, all of the studies are cross-sectional and only the Moch-Sibony (1984) study carefully screened children for normal hearing. The Heft (1979) study relied upon observer ratings of home noise levels, no actual noise measurements were taken.

The Hambrick-Dixon (1988) results are particularly complex and difficult to interpret. One possible explanation for the inconsistency between her results and those of other researchers is that she measured the ability of children to detect a visual signal using tachistoscopic presentation times (100 msec). Thus rather than

Table 4. Effects of noise on auditory discrimination/speech perception

Author(s)	Outcome	Noise Source/Level	Sample Population (n)	Basic Result
Chronic noise				
Cohen et al. (1973)	WAD	Traffic and street. 55-66 dBA.	(54) grades 2-5.	Noise associated with poorer auditory discrimination.
Cohen et al. (1980)	WAD	Aircraft. 95 dBA peak.	(262) grades 3-4.	No effects of noise on auditory discrimination.
Cohen et al. (1986)	WAD	Aircraft. 95 dBA peak.	(165) grade 3, new sample.	No effects of noise on auditory discrimination.
Moch-Sibony (1984)	MP	Aircraft. 29 vs 54 SIL.	(80) kindergarten.	Noise associated with poorer auditory discrimination.
Acute noise				
Blue & Vergason (1975)	GFW	Recorded sounds (unspecified). 55 dBA.	(34) grades 1,3.	Race x Noise interaction: Black children's performance affected more negatively by noise than was white children's performance.
Nober & Nober (1975)	WAD	Recording of classroom noise vs ambient noise. 39.5-64.7 dBA.	(39) ages 5-7 yrs (healthy control, retarded, and speech-deficit).	Fewer errors when tested in quiet vs. normal classroom noise levels. Control and retarded children performed worse in noise than in quiet; speech-deficit group performed worse in noise than in quiet, but the effect was not significant.
McCroskey & Devens (1977)	WAD	Classroom noise recording. 4 dBA above ambient classroom noise	Unavailable.	Noise associated with decrements in auditory discrimination.
Glenn et al. (1978)	Speech discrimination	Recorded hospital sounds. 75 dB SPC (typical for hospitals).	(21) ages 9-14 yrs (institutionalized MR).	Noise mask significantly degraded speech discrimination.
Laraway (1985)	Digit discrimination	Intermittent white noise. 80 dB SPC.	(46) ages 5-21 yrs (CP, healthy controls).	Noise mask degraded performance of CP children but not controls. Noise effects greatest in younger (< 7 yrs) children.
Laskey & Tobin (1973)	Message comprehension	Speech and white noise. 74 dB SPC.	(22) ages 6-8 yrs (possible LD, non-LD controls).	Speech, but not white noise, interfered with auditory message comprehension in LD children. Control children unaffected by noise.

Note: WAD = Wepman auditory discrimination test, GFW = Goldman-Fristoe-Woodcock auditory discrimination task, MP = Massiot Phillips auditory discrimination test, SIL = speech interference level, LD = learning disabled, CP = cerebral-palsied, MR = mentally retarded.

measuring sustained visual attention, Hambrick-Dixon probably measured signal detectability.

As expected given the physical properties of noise, considerable attention has been given to auditory information processing among children exposed to chronic or acute noise sources. One of the cognitive strategies that children may learn in order to adapt to the distracting properties of chronic noise is to filter or tune out unwanted auditory stimuli. The tendency of children in noisy environments to tune out noise may become overgeneralized, such that various types of acoustic stimuli, including speech, are not attended to carefully (Deutsch, 1964). In a direct

test of the tuning out hypothesis, Cohen et al. (1973) compared the ability of children living in quiet and noisy apartments (proximity to a freeway) within the same building to discriminate between similar sounds under quiet conditions. Cohen et al. (1973) as well as Moch-Sibony (1984) found an association between chronic noise exposure and auditory discrimination (see Table 4). Both of these studies had good controls for socioeconomic status, and pre-screened children for hearing loss. Moreover, Cohen et al. (1973) showed that with longer exposure durations, the association between noise and deficits in auditory discrimination became stronger.

Table 5. Effects of noise on resistance to auditory distractors

Author(s)	Outcome	Noise Source/Level	Sample Population (n)	Basic Result
Chronic noise				
Cohen et al. (1980)	Cross-out letters in ambient or distracting (story recording) condition.	Aircraft. 95 dBA peak.	(262) grades 3-4.	Noise × Month enrolled interaction: with less than 2 yrs enrollment, noisy-school children performed better than quiet-school children under distraction. Between 2-4 yrs enrollment, no noise effects. With more than 4 yrs enrollment, noisy-school children performed worse than quiet-school children.
Cohen et al. (1981)	Cross-out letters in ambient or distracting condition.	Aircraft. 95 dBA peak.	(163) grades 3-4, longitudinal sample.	With 2-4 years enrollment, noisy-school children were less distracted than quiet-school children. With more than 4 yrs enrollment, performance was nearly the same across conditions.
Cohen et al. (1986)	Cross-out letters in ambient or distracting condition.	Aircraft. 95 dBA peak.	(165) grade 3, new sample.	Children attending noisy schools for 2-4 yrs were less distracted than their quiet-school counterparts. However, after 4 yrs enrollment, performance was nearly the same across conditions.
Cohen et al. (1981)	Cross-out letters in ambient or distracting condition.	Aircraft. 16 dBA reduction in noise-abated classrooms.	(163) grades 3-4, longitudinal sample.	No effects of noise abatement on distractibility.
Hambrick-Dixon (1986)	Weschler IQ task and match animals with color disks in quiet or noise conditions.	Train. 108 dBA peak.	(109 black) ages 4-6 yrs.	Children from noisy daycare performed better in noisy than in quiet conditions. The opposite was found for children from quiet daycare centers.
Heft (1979)	Figure discrimination in matching task in quiet or noise.	Story reading. Noise ratings: 1 = low to 7 = high.	(94) ages 4-7 yrs.	Auditory distraction had less of a negative effect on children from noisy homes than on children from quiet homes.
Acute noise				
Tumure (1970)	Performance and glances away from a visual discrimination task.	Recording of child songs/stories. 60 dBA.	(30) ages 5.5, 6.5, 7.5 yrs.	No noise effects on glances, but performance worse in noisy than in quiet conditions.
Steinkamp (1980)	Multiple perceptual and cognitive tasks.	Classroom sounds and gadgets. Ambient noise.	(24) ages 6-8 yrs (hyperactive, non-hyperactive controls).	Classroom noise and distracting visual materials caused deficits on most tasks. No interaction with hyperactivity.

In two subsequent studies, Cohen et al. (1980; 1986) were unable to replicate these findings on noise and auditory discrimination using a different noise source (aircraft as opposed to traffic). The traffic noise study (Cohen et al., 1973) also drew primarily from working class families; whereas the airport study was conducted in a poverty area. Using a different auditory discrimination task, however, did reveal deficiencies in auditory discrimination in children chronically exposed to noise from airports (Cohen et al., 1986). Children were presented a constant signal (man reading a story) superimposed against four different white noise backgrounds. The task was

to choose the optimum signal to noise ratio. Children who attended noisy schools for longer periods were significantly poorer at this signal to noise discrimination task (see Table 4).

Not surprisingly, the acute noise experimental studies in Table 4 indicate that children have difficulty with auditory discrimination during acute noise exposure (Blue & Vergason, 1975; Glenn et al., 1978; Laraway, 1985; Nober & Nober, 1973). Thus noise can directly interfere with children's ability to discriminate between meaningful auditory stimuli. Noise, particularly irrelevant speech, also interferes with comprehen-

sion of spoken language (Glenn et al., 1978; Laraway, 1985; Lasky & Tobin, 1973). The Glenn et al. (1978) data are noteworthy because the researchers used simulated recordings of an institutional setting for the mentally retarded as their noise 'mask'. Typical, ambient levels from the institution were sufficient to produce marked deficits in discriminating speech sounds among mentally retarded children.

Although there are clear overall trends showing that concurrent noise can mask auditory discrimination, as well as speech, there may be individual differences in these effects. Blue and Vergason (1975) found racial differences in auditory discrimination with black children being more adversely affected than white children by concurrent noise. This study was conducted in the Southeastern United States and may not have controlled for the dialect used in stimulus materials. Laraway (1985) reported that only cerebral palsied children were adversely affected by a noise mask in a task in which children were asked to repeat auditorily presented digits. Lasky and Tobin (1973) revealed that only children with suspected learning disabilities had difficulties in tracking an auditory signal against a background of competing, irrelevant speech. The latter study also showed that speech, but not white noise of a similar volume, interfered with message comprehension.

An interesting and provocative question raised by Deutsch's original hypothesis and some of the subsequent empirical work is whether children chronically exposed to noise become so adept at filtering out noise, that they become resistant to its distracting properties. A number of studies shown in Table 5 present suggestive evidence in support of this hypothesis of differential resistance to noise distractors. However, the data are complex.

Kindergarten children from noisy homes were less distracted by irrelevant speech during a visual discrimination task than those from quiet homes (Heft, 1979). In this task, children selected one of several figures that correctly matched a standard figure. Cohen and colleagues (1980) found a similar pattern of results, but only for elementary students exposed to aircraft noise for two years or less. For those exposed longer, auditory distraction during a visual search task (crossing out e's in a text above reading level of the child) interfered more with the performance of noisy-

school children than it did for quiet-school children. This effect was also replicated in a different sample (Cohen et al., 1986). Hambrick-Dixon (1986) uncovered an even more complex pattern of data on a visual coding task among very young children. In this task preschool children placed colored discs next to animal drawings according to an initial set of model comparisons. For children from noisy daycare centers, performance on this task was better under noisy testing conditions than quiet ones; whereas for children from quiet daycare centers, performance was superior during quiet testing conditions than under noisy ones.

Thus, although there is some evidence that children chronically exposed to noise are less distractable by auditory stimuli during a task, with very long exposure (4+ years), they appear to lose this advantage over non-noise-exposed children. Children exposed for short periods of time to chronic noise, may be able to gate out auditory distractors more effectively during tasks; whereas children exposed for long periods of time, may lose this gating ability. This could occur because despite sustained efforts to gate out unwanted sounds, children learn that this coping strategy is ultimately ineffective since the noise remains as a potent distractor.

The type of task, type of noise, and some individual difference variables also may influence whether concurrent auditory stimuli are distracting during task performance. For example, although both Heft (1979) and Cohen et al. (1980; 1986) found that concurrent speech distracted children during a visual search task (finding target objects in a matrix, crossing out target letters in text, respectively), Hambrick-Dixon (1986) had no main effect of a distractor (background noise of a daycare free play period) on performance of a visual matching task (placement of colored discs next to animal drawings). Turnure (1970) found a distracting effect of speech on school children's performance on a visual discrimination task (choosing the odd geometric shape out of three stimuli). However behavioral manifestation of distraction (glancing up) was not observed. Zentall and Shaw (1980) found that classroom noise recordings did not affect a visual letter search task for normal children and degraded performance for hyperactive, elementary-aged children. Finally, Steinkampf (1980) found that the combination of recorded classroom sounds

Table 6. Effects of noise on memory

Author(s)	Outcome	Noise Source/Level	Sample Population (n)	Basic Result
Chronic noise				
Hambrick-Dixon (1986)	Serial, incidental, visual, paired-associates learning.	Train. 108 dBA peak.	(109 black) ages 4-6 yrs.	No noise effects.
Heft (1979)	Incidental memory of visual stimuli.	Noise ratings: 1 = low to 7 = high.	(94) ages 4-7 yrs.	Higher household noise level associated with poorer incidental memory.
Acute noise				
Fenton et al. (1974)	4 number digit-span.	White noise. 22-72 dBA.	(10 male) ages 9-11 yrs (LD and non-LD).	More errors made in the high noise than in the low noise conditions.
Hygge (1993)	Recall and recognition of reading passage.	Recorded simulations of aircraft, train, traffic, and verbal noise. 66-76 dBA.	(417) ages 12-14 yrs.	Within-subjects analyses revealed a marginal Noise x Source interaction: recall on difficult questions was lower among children in aircraft and traffic noise conditions than in control conditions; no differences in recall in train and verbal noise conditions relative to control condition. Between-subjects analyses also revealed a Noise x Source interaction: recall on difficult questions was lower among children in aircraft noise conditions than in controls; other noise sources did not affect recall. No noise effects on recognition task. Individual differences in learning ability did not moderate noise effects.
Johansson (1983)	Paired-associates learning and letter memory.	White noise. 51 dBA continuous; 55-78 dBA intermittent.	(66) age 10 yrs.	No noise effects.

Note: LD = learning disabled.

played at normal volume and the presence of interesting gadgets were distracting for several tasks among normal and hyperactive boys. Because the latter study did not separate ambient noise from visual distractors, the specific effects of noise cannot be determined.

It is difficult to discern any clear patterns in the above findings on acute, concurrent noise and distraction among children. Speech, as opposed to background noise (e.g., recordings of classroom noise), may be more distracting during task performance. Unfortunately since no studies have used the same task with different aged children, we cannot infer any developmental trends from the data. However it is noteworthy that studies showing no effects tested the youngest children.

Summary

Children chronically exposed to noise may suffer from attentional deficits. Although suggestive,

the work in this area suffers from sufficient methodological flaws (e.g., controls for SES) to prohibit definitive conclusions. Children chronically exposed to noise develop cognitive strategies to cope with the interruptive, distracting influence of noise. Some data suggest that children learn to ignore or tune out auditory stimuli if they have been chronically exposed to noise. At least during the first few years of exposure, children from noisy residential areas appear to be more resistant to acute auditory distractors, presumably because of their enhanced ability to tune out auditory stimuli. These same children may suffer deficits in auditory discrimination. Acute noise distracts children during cognitive task performance, especially when the distractors contain meaningful speech. These acute auditory distraction effects may be more problematic for certain subgroups of children, especially those with some pre-existing cognitive deficits. More research, particularly on groups potentially at risk should be a high priority.

Memory

The noise and memory literature on children (Table 6) is sparse but generally in agreement with the adult literature (Cohen et al., 1986; Smith, in press). There appears to be little or no effects of noise on simple memory tasks from chronic exposure (Hambrick-Dixon, 1986) or acute exposure (Johansson, 1983). However, if sufficient processing demands are placed upon memory, deficits begin to appear in children exposed to noise (Fenton et al., 1974; Hygge, 1993).

Hygge's (1993) experimental findings (see Table 6) are interesting because he compared relatively easy and difficult memory tasks under quiet and noisy conditions, finding that only the difficult tasks were sensitive to noise exposure. Heft's (1979) incidental memory deficits are also noteworthy because they fit with a typical noise and memory finding in adults. The adult incidental memory studies have been interpreted as indicative of attention narrowing or focusing on dominant stimuli (Cohen et al., 1986). Attention narrowing appears to be common under arousing conditions in general (Broadbent, 1971) and under noise specifically (Hockey, 1979). Greater attention to more central cues could lead to poorer encoding of more peripheral material.

Summary

Although there is little research on children's memory under chronic or acute noise conditions, the data are generally in accord with the adult literature on the subject. Noise exposure has little if any effect on children's short term or working memory. Memory tasks that put especially demanding loads on working memory, however, may show some deficits. Narrowing of attention to more central cues under noise may cause poorer memory for incidental information. The potential role of attentional processes in noise-related memory effects warrants further scrutiny.

Intellectual Achievement

Given the reasonable possibility that chronic noise exposure interferes with auditory discrimination and attentional mechanisms, it is not surprising that several researchers have uncovered evidence linking noise exposure with deficits in reading. It is important to note at the onset that unlike chronic effects of noise on cognition, studies of reading and achievement confound chronic and acute noise exposure since they all have relied

upon archival records of achievement tests. As indicated in Table 7, however, the handful of studies of acute noise on intellectual achievement find few if any negative effects. This suggests, indirectly, that the community noise and achievement findings are probably caused by chronic and not acute exposure.

Two clusters of chronic noise associations with intellectual achievement are shown in Table 7. The first group of studies, conducted primarily by Wachs and colleagues, have explored the impacts of early exposure to noise in the home on infants and toddlers. Their work in general finds positive evidence that noise can interfere with normal cognitive development. The findings have been replicated and extended in longitudinal studies (see Wachs & Gruen, 1982, for an overview of this research program). Measurements of cognitive development affected by noise include mental representations of objects, use of objects as tools to achieve goals, and relating words to objects.

One major weakness in Wach's and other research on noise and young children (e.g., Heft, 1979) is reliance on observer ratings of noise exposure rather than actual measurement of physical sound levels. Recently, however Wachs (1988) has validated this measurement approach against decibel meter readings. Another finding that indicates that the effects are due to noise is that access to a secluded quiet room or shelter within the home largely ameliorates the associations between noise ratings and measures of cognitive development (Wachs & Gruen, 1982). Michelson (1968) has found the same buffering effect of a stimulus shelter with home noise levels on elementary school aged children's reading ability. These data on buffering effects of quiet, secluded study spaces in noisy homes raise the possibility, however, that some of the apparent effects of residential noise exposure on cognitive development could be due to residential crowding. It is obviously difficult to disentangle the ecological covariation between these two environmental conditions. Moreover, both of them appear to be associated with deficits in reading acquisition in young children (Evans et al., 1990).

The second group of studies in Table 7, has examined the association between chronic noise exposure at school and/or home with standardized measures of reading and other intellectual achievement tests. With two exceptions, the data

Table 7. Effects of noise on intellectual achievement

Author(s)	Outcome	Noise Source/Level	Sample Population (n)	Basic Result
Chronic noise				
Bronzaft (1981)	Reading.	Train. 6-8 dBA sound reduction in noisy classrooms.	(955) grades 2-6.	After sound reduction with insulation on noisy side of school, students' reading scores on noisy side of school were equivalent to those of students on quiet side of school. In the year before insulation, students on noisy side of school had worse reading scores than students on quiet side of school.
Bronzaft & McCarthy (1975)	Reading.	Train. 59-89 dBA.	(161) grades 2, 4, 6.	Students' reading scores lower on noisy side of school than on quiet side, especially in higher grades.
Cohen et al. (1973)	Reading.	Traffic and street. 55-66 dBA.	(54) grades 2-5.	Noise associated with greater reading deficits in children living in apartments for 4 or more years.
Cohen et al. (1980)	Reading and math.	Aircraft. 95 dBA peak.	(262) grades 3-4.	No noise effects.
Cohen et al. (1981)	Reading and math.	Aircraft. 95 dBA peak.	(163) grade 3-4, longitudinal.	No noise effects.
Cohen et al. (1981)	Reading and math.	Aircraft. 16 dBA sound reduction in noise-abated classrooms.	(163) grade 3-4, cross-sectional.	Noise abatement results in 3rd grade only. Third graders in noise-abated classrooms performed better in math than 3rd graders in non-abated classrooms; 3rd graders in noise-abated classrooms also performed better in reading, but not significantly so.
Cohen et al. (1986)	Reading and math.	Aircraft. 95 dBA peak.	(165) grade 3, new sample.	No noise effects.
Gottfried & Gottfried (1984)	BSID, OP, MS, TELD	Noise ratings: 1 = normal level voices in home for 15 min. period to 4 = noise level voices in home for more than half 15 min. period.	(130) 12 mon. infants tested every 6 mon. up to 42 mon.	Higher household noise associated with lower scores on OP at 12-18 mon., on TELD at 39 mon., on BSID at 18 mon., and on MS scores at 42 mon.
Green et al. (1982)	Percent reading below grade level.	Aircraft. 96.2 dBA peak.	(8,240) grades 2-6.	Greater percentage of noisy-school children read below grade level. Effects strongest in higher grades.
Lukas et al. (1981)	Reading and math.	Traffic and street. 70 dBA peak.	(2500) grades 3,6 (100 classes sampled).	Reading scores lower for 3rd and 6th graders in noisier classes. Math scores lower in students in noisier 3rd grade classes, but higher in 6th grade students in noisier classes.
		Ambient classroom and community. 45-75 dBA.		Inverse correlations between community noise and math and reading scores were similar to but less consistent than those between classroom noise and math and reading scores. There also was a synergistic effect of home and school noise on reading.

Table 7. *Continued*

Author(s)	Outcome	Noise Source/Level	Sample Population (n)	Basic Result
Wachs et al. (1971)	IPDS	Noise ratings: 1 = normal level voices in home for 15 min. period to 4 = noise level voices in home for more than half 15 min. period.	(102) ages 7, 11, 15, 18, 22 mon.	Higher household noise associated with lower IPDS scores.
Wachs (1978)	SB	Ratings of noise: same as Wachs et al. (1971).	(23) ages 2-3 yrs. longitudinal.	Higher household noise associated with poorer SB performance in boys, no significant effect in girls.
Wachs (1979)	IPDS	Ratings of noise: same as Wachs et al. (1971).	(31) ages 2-3 yrs. longitudinal.	Higher household noise associated with lower IPDS scores in boys and higher IPDS scores in girls.
Wachs & Gandour (1983)	IPDS	Ratings of noise: same as Wachs et al. (1971).	(100) ages 7, 11, 15, 18, 22 mon.	Higher levels of household noise associated with lower IPDS scores, particularly in fussy and irritable infants.
Michelson (1968)	Language, spelling, and math.	Home environment ratings. Scale unavailable.	(710) grades 1-5.	Noise associated with language and spelling difficulties. Noise not associated with math achievement.
Maser et al. (1978)	Reading and math.	Aircraft. 90 dBA peak.	(1917) grades 3, 5, 7, 10.	Noise associated with reading and math deficits in 7th and 10th graders, but only marginal effects on 5th graders. Children with lower aptitudes were most adversely affected by noise.
Acute noise				
Christie & Glickman (1980)	SPM	Recorded classroom noise. 40 and 70 dBA.	(156) grades 1, 3, 5.	Noise x Sex interaction: Boys performed better in noisy than in quiet conditions; girls performed better in quiet than in noisy conditions.
Johansson (1983)	Reading and math.	White noise. 51 dBA continuous, and 55-78 dBA intermittent.	(66) age 10 yrs.	Noise x Intelligence interaction on multiplication and reading performance. Above-average intelligence children solved more multiplication problems in noise than in quiet; below-average intelligence children showed the opposite trend, but noise effects were not significant. Below-average intelligence children tended to have poorer reading speed under noise; there was little difference in reading performance between noise groups with above-average intelligence.
Kassinove (1972)	Math.	Recorded child stories and music. 70-80 dBA.	(80) grades 3,6.	No noise effects on response latency, accuracy, or time-out from task.
Slater (1968)	Reading and math.	Ambient classroom noise, music, stomping and banging, tractor-mower, or quiet crossed with taped white noise. 45-90 dBA and 50-80 dBA white noise.	(263) grade 7.	No noise effects on speed or accuracy.

Table 7. *Continued*

Author(s)	Outcome	Noise Source/Level	Sample Population (n)	Basic Result
Weinstein & Weinstein (1979)	Reading.	Classroom: Ambient noise levels during early (noisy) and late (quiet) time of day. 47-60 dBA.	(60) grade 4.	No noise effects.
Zentall & Shaw (1980)	Math.	Taped noise from 2nd grade class. 64 and 69 dBA.	(48) grade 2 (hyperactive, normal controls).	Noise x Hyperactivity interaction: Hyperactive children performed marginally worse in high noise than in low noise; non-hyperactive children performed worse in low noise than in high noise conditions.

Note: BS = Bayley scales of infant development, OP = object permanence scale, MS = McCarthy scales of children's abilities, TELD = test of early language development, IPDS = Piagetian-type measure of infant psychological development, SD = Stanford-Binet test of intelligence, SPM = standard progressive matrix test.

converge on the conclusion of a relation between community noise exposure and reading ability. Several of the studies have good controls for sociodemographic characteristics in the samples and some have screened out children with auditory deficits. Moreover, Green et al. (1982) found a dose response function between noise exposure and reading deficits. Furthermore, the effects in the Bronzaft studies (Bronzaft, 1981; Bronzaft & McCarthy, 1975) cannot be attributed to self-selection. Children were not assigned in any systematic manner to classrooms on the noisy or quiet side of a building located next to elevated train tracks. On the other hand, all of the studies except for Bronzaft (1981) and Cohen et al. (1981) are cross-sectional and neither of these longitudinal studies are prospective. The Bronzaft (1981) findings are particularly important because they indicate that classrooms on the side of an elementary school near elevated train tracks that previously had lower reading scores in comparison to classrooms on the opposite side of the building (Bronzaft & McCarthy, 1975) no longer differed in reading scores following noise insulation in the schools and on the tracks.

The two studies that have not found reliable noise effects on reading may have poor statistical power. Both Cohen et al. (1980; 1986) and Moch-Sibony (1984) tested children from different schools, with different teachers, and in the former case from different school districts. In addition, both restricted their analyses to children from lower grades and did not attempt to tease out the

effects of noise on children of differing ability.

As indicated in several of the citations in Table 7, children in higher grades appear to be more negatively affected by noise exposure on reading than their younger counterparts (cf., Cohen et al., 1973; Green et al., 1982; Lukas et al., 1981; Maser et al., 1978). Children who have lower aptitude or other difficulties may be more vulnerable to the harmful effects of noise on reading (Maser et al., 1978). We also noted earlier several distraction studies indicating more disruptive effects on children with various learning deficiencies. Finally, Lukas and colleagues (1981) uncovered a significant synergistic effect of home and school noise exposure on reading scores.

Summary

Acute noise exposure appears to have little effect on reading and other intellectual activities. During early development, however, residential noise appears to delay cognitive development. In addition, chronic exposure to noise has been associated with reading deficits in seven out of nine studies, particularly for children in higher elementary school grades. There is also evidence that children with lower aptitude and those who also live in noisier homes appear more susceptible to the association of chronic noise exposure at school with reading deficits. The latter trend is interesting to consider in light of attentional data also showing more negative effects of noise exposure on children with pre-existing cognitive deficits.

DISCUSSION

Overview

We know with a good deal of certainty that chronic exposure to noise is associated in children with modest elevations of resting blood pressure, attentional deficiencies, and deficits in reading. Other effects suspected from chronic noise exposure include diminished task motivation, deficits in auditory discrimination, shifts in resistance to auditory distractors, poorer memory when high information processing demands are present, and deficits in infant cognitive development. The latter group of suspected effects include inconsistent data in some cases (auditory discrimination, resistance to distraction) or trends that have only been uncovered in one or two studies (motivation, memory, infant cognitive development). Tables 1-7 provide summary information that forms the bases for these conclusions.

Two major methodological shortcomings are prominent in the literature we have reviewed. Most critically, there is a total lack of prospective, longitudinal designs in this research area. Prospective, longitudinal studies are the strongest, *quasi*-experimental designs that can be applied in field studies and help deal with the host of threats (e.g., self-selection, confounding third variables) that plague correlational designs (see Cohen et al., 1986; Evans & Lepore, in press, for further discussion of methodological problems in field studies of environmental stressors). Such prospective studies must include well matched comparison groups and collect important personal data known to relate to outcomes of interest. Besides their utility as potential control variables in nonexperimental study designs, background variables can enhance statistical power by reducing unexplained variance in the outcome measure of interest. Studies on cardiovascular outcomes, for example, need to collect data on family history of hypertension. Research on reading should collect information on parental education levels and child's intelligence. Prospective, longitudinal designs will have to contend, however, with the potential interfering effects of selective attrition. As documented earlier, Cohen and his colleagues (1981), in one of only two longitudinal studies of noise and children, found that a year later children with the highest levels of blood pressure in their initial

cross-sectional analysis of quiet and noisy schools had moved out of the area. No such selective attrition was found among children in quiet schools.

The second major methodological shortcoming in nonauditory noise research and children has been lack of precision in two aspects of procedural conditions during testing. Testing conditions must be uniform and quiet. Reliance on archival measures of reading, for example, confounds acute with chronic noise exposure since ambient noise sources are likely to be present during the conduct of achievement tests. Testing must occur under quiet conditions in order to determine whether chronic noise affects reading or some other outcome of interest. More thorough audiometric screening is needed in nonauditory studies of noise and children to insure that the effects are not due to hearing loss.

Ecological Perspective

The purpose of this section is to outline some major conceptual shortcomings in the existing work on the nonauditory effects of noise on children and to lay out a preliminary research agenda. An ecological perspective (Bronfenbrenner, 1979) would significantly advance our understanding of this topic. Such a perspective includes greater attention to temporal issues plus the social and environmental contexts in which chronic noise exposure occurs. It also entails examination of the underlying, mediational processes that may link some of the psychophysiological, motivational, and cognitive processes related to chronic noise exposure.

Temporal parameters

Foremost, there has been a severe lack of developmental analyses, except in a few reading studies and in some of Wach's work on infant development in the home environment (see Table 7), of the effects of chronic noise on children. Developmental research approaches are critical in noise studies because it is highly likely that noise has differential impacts on physiological, cognitive and motivational processes as a function of developmental status. Consider for example reading acquisition. It is well established that reading acquisition depends upon the development of certain language competencies (e.g., phonological awareness) that are age

dependent (Mann & Brady, 1988). Noise exposure prior to or following the development of phonological awareness may not affect reading acquisition in the same way as noise exposure during the critical period of phonological awareness learning. Unless a developmental approach is added to noise research, such questions cannot be addressed.

A related but distinct conceptual limitation has been neglect of temporal parameters such as age at time of exposure and history of exposure to noise. For example, several studies on resistance to distractors from noise indicate the effects are contingent upon noise exposure history (see Table 5). Children exposed to ambient noise levels for shorter periods of time appear to be more resistant to the distracting properties of noise (see Table 5). These findings could relate to work on motivational deficiencies from prolonged noise exposure. Perhaps children attempt to filter out noise during early periods of exposure but eventually give up on this strategy. Duration effects could also relate to the specificity of resistance to auditory distractors. It would be interesting, for example, to investigate children's ability to filter out aircraft noise versus white noise or irrelevant speech, as a function of length and type of chronic noise exposure.

Unfortunately, we cannot disentangle age effects from exposure duration effects. For example, the apparently stronger linkages between chronic noise exposure and reading scores among older children (see Table 7) could be a function of a critical period of exposure or the result of longer, cumulative adverse impacts. Related to this latter option, we know nothing at this stage about the long-term effects of early childhood exposure to noise. What happens in later childhood or adolescence to children who spend all or part of their early years attending school or living near an airport or busy street?

Context

Greater attention to the ecological context in which chronic noise exposure occurs may prove fruitful for future research on noise and children. This ecological context might include more ecologically valid noise exposure estimates, attention to the indirect effects of noise on children via adult caregivers, and measurement of other social and environmental conditions covarying with chronic noise exposure. With one

exception (Lukas et al., 1981) none of the field studies of noise and children have attempted to calculate overall noise exposure. It may be recalled that Lukas and colleagues found a synergistic effect of home and school noise exposure on reading.

Furthermore, the noise estimates that researchers have relied upon do not take into account children's mobility, exposure to noise sources in the home, or the attenuation properties of the structures they inhabit.

Nearly all of the work on noise and children involves comparisons between noisy and quiet settings. With one exception, Green et al. (1982), there is no information on dose response functions. Besides its evidentiary value, dose response curves would have public policy importance. We currently are unable to provide clear statements about what level of noise is harmful for children or to say what the efficacy would be of providing specific sound attenuation interventions.

Not only are children attending school or residing in homes in noisy areas exposed to noise but so are their principal caregivers. The behaviors of caregivers in noisy settings could indirectly influence children's responses to noise (Bronfenbrenner, 1979). For example, perhaps parents in noisy homes do not speak to their children or read to them as often as parents in quieter neighborhoods. Classroom observations and teachers' self-reports indicate that aircraft or train noises interrupt teacher lecturing (Crook & Langdon, 1974; Kyzar, 1977; Moch-Sibony, 1974), in one study causing a 10% reduction in total teaching time (Bronzaft & McCarthy, 1975). It is also well documented that teachers in noise-exposed classrooms report greater annoyance and fatigue during the school day in comparison to teachers from quiet classrooms (Crook & Langdon, 1974; Ko, 1979; 1981; Sargent et al., 1980). Therefore some of the adverse effects of noise on child development could be mediated through the negative impacts of noise on the child's primary caregivers. Parents and teachers may have less patience and energy to devote to children because of the adverse effects of noise on themselves. More directly, noise may alter the manner in which parents and teachers instruct children, altering reading or speaking patterns. Recent data indicate that parent-child interactions may be affected by household noise levels. Parents from noisier homes appeared less

interested in their children's activities and talked less with their children (Wachs, 1989; Wachs & Camli, 1991). Controls for education levels of the mother did not change these findings.

Ambient noise exposure rarely occurs in isolation of other social and environmental problems. Noisy environments frequently covary with crowding and pollution and are often part of the fabric of poverty, including substandard housing, conflictual households and various other psychosocial strains. Although the ecological covariation of noise with other adverse environmental and social factors makes it difficult to isolate the effects of noise on children, we should be mindful that the harmful effects of noise may be amplified by the context in which noise is often embedded. It may be precisely those children who develop under such impoverished physical and social circumstances who are most vulnerable to the harmful effects of noise (Bronfenbrenner, 1979; Evans et al., 1990). We have recently found among adults, for example, that the negative effects of residential crowding on psychological distress are significantly worsened by chronic strains associated with poverty (e.g., insufficient utilities, poor housing quality, financial insecurities) (Lepore et al., 1991).

Noise levels may also operate within a context of important individual differences among children. There is some evidence that some children are more at risk for adverse noise effects on cognitive development. Less intelligent children's math and reading performance appears more sensitive to noise exposure (Johansson, 1983; Maser et al., 1978). Studies of young children and infants suggest greater susceptibility to chronic noise-related problems among boys in comparison to girls (Wachs, 1978; 1987; 1989). On the other hand, girls may be more distracted by acute noise exposure (Christie & Glickman, 1980; Hambrick-Dixon, 1988). Cognitive performance during acute noise appears to be disrupted more by noise for individuals with pre-existing learning deficits (cerebral palsy, learning disabled).

In addition to alerting researchers and policy makers to the potential of subgroups of children at high risk for negative effects of noise, these findings also have another important implication. Some of the small or even conflicting nonauditory effects of noise reviewed herein may be conservative estimates of noise effects since they by and large have not examined interactive effects.

While in some cases there may be little if any overall noise effects on children, it would be erroneous to conclude from such data profiles that noise is an inconsequential environmental problem for children. There may be large segments of the child population whose development may be significantly compromised by noise exposure early in life.

Mediational processes

Another area of future research that might emanate from an ecological perspective on noise and children is greater scrutiny of the potential interplay among the various psychophysiological, cognitive, and motivational processes that appear to be affected by chronic noise exposure. Cohen and his colleagues (1973) examined Deutsch's (1964) hypothesis that children chronically exposed to noise may learn to tune out auditory stimuli indiscriminantly and thus not pay sufficient attention to speech. They found that children from noisier apartments were deficient in auditory discrimination. Of particular interest, this deficiency significantly accounted for the poorer reading abilities of the noise-exposed children. This study stands alone as the only analysis of an underlying process to explain how noise affects children.

Given the findings (see Table 4) that noise can mask speech and evidence that speech perception and other linguistic skills such as phoneme awareness are critical precursors to reading acquisition (Mann & Brady, 1988), more work is called for on the effects of chronic noise exposure on psycholinguistic processes and their potential mediating link with reading. Other pathways warranting further investigation include those between chronic noise exposure, motivation, attention, and reading.

There are also plausible interconnections among chronic noise exposure and several of the cognitive processes we have reviewed. For example, people chronically exposed to noise may become more resistant to the distracting effects of acute noise exposure during a task because they can ignore or filter out auditory distractors. This ability may occur as a result of learning to tune out or filter auditory sounds. Thus one would expect a relation between the ability to ignore auditory distractors and deficits in auditory discrimination associated with chronic noise exposure. Analogously, we would expect a mediational pathway

between chronic noise exposure, attentional focusing and deficits in incidental memory performance.

Thus rather than only treating different outcome variables such as reading, attentional processes, and resistance to distraction as separate correlates or effects of noise exposure, more thought and careful analyses are required to investigate how these variables may form causal links to one another. In other words, both the direct and indirect pathways of the nonauditory effects of noise on children need to be investigated. From a theoretical and public policy perspective, this is perhaps most crucial in the case of reading. Although stronger data on the adverse effects of chronic noise exposure on reading would be valuable from an evidentiary point of view, what is of paramount importance now is a shift in focus to explanations of why and how chronic noise adversely influences reading acquisition.

There may also be some potent interplay among psychophysiological processes and some of the cognitive strategies apparently influenced by chronic noise exposure. For example, presumably it takes some effort to tune out or ignore noise. Experimental data as well as field studies with adults indicate that cognitive efforts to maintain task performance during noise come at a price of heightened sympathetic arousal (Tafalla & Evans, 1993; Welch, 1979). When performance suffers under noise, slight or no sympathetic arousal is apparent. However, if performance is maintained under noise which is possible except under tasks of very high load demands on attention and working memory (Cohen et al., 1986; Smith, *in press*), then indices of sympathetic arousal should be substantially elevated during noise exposure.

The associations between chronic noise exposure in children (see Table 1) and heightened blood pressure raise several important questions about mechanisms. For example, are blood pressure elevations caused by repeated sympathetic arousal induced by the distracting and interfering properties of community noise conditions? Alternatively, are the elevations mediated by adrenocortical activity and thus primarily indicative of chronic stress? To our knowledge, no analyses of various psychoneuroendocrine pathways between noise and blood pressure elevations have been investigated. Given the central role of cognitive appraisal in psychological

stress, it would also behoove researchers to examine whether psychosocial factors such as perceived control, self-confidence to ignore/tune out noise, or annoyance, moderate the effects of noise on blood pressure and other psychophysiological processes among children.

Another fruitful area of psychophysiological research would be to investigate the potential role of chronic noise exposure in cardiovascular reactivity. Individual differences in reactivity to standard psychosocial elicitors of stress (e.g., mental arithmetic) may be predictive of cardiovascular disease (Krantz & Manuck, 1984; Matthews et al., 1986). Research on cardiovascular reactivity in both adults and children has ignored the potential etiological role of chronic exposure to environmental stressors. More detailed analyses, focusing on possible behavioral toxicological effects of in utero or neonatal noise impacts are also called for. This is especially pertinent in light of contemporary medical practices such as ultra sound monitoring or placement of premature infants in neonatal intensive care units.

Large numbers of children both in America and, in rapidly growing numbers in the Third World, are being exposed to levels of ambient noise that are not only a threat to hearing but may have harmful effects on physiological and cognitive development. The potential for harmful effects from chronic noise exposure on children's development is great; what we know with certainty about the problem is, unfortunately at the moment, insufficient. At the same time, there is a foundation of evidence clearly suggesting potentially harmful effects from chronic noise exposure among children. We also have enough data on hand to formulate preliminary models of underlying, mediating mechanisms that could account for the effects of noise. It is also clear that more longitudinal work with prospective designs is crucial to definitively demonstrate the relationships between chronic noise exposure and children's development. Such designs afford stronger internal validity given the impossibility of randomly assigning children to varying community noise levels. Longitudinal designs allow us to examine changes in behaviors over time plus provide the opportunity to examine whether self-selection has occurred prior to noise exposure.

ENDNOTE

This article is based in part on earlier presentations at the Fifth International Congress on Noise as a Public Health Problem, Stockholm, Sweden and A Strategy for Noise Prevention in the 90's, American Speech and Hearing Association, Washington, DC. Preparation of this article was partially supported by the National Heart Lung and Blood Institute, RO1 HL47325-01A1, the Nordic Noise Council, and the Swedish Environmental Protection Board.

ABSTRACT. The percent of students reading below grade level from 1972 to 1976 was regressed on racial, socioeconomic, educational, and noise level variables for all elementary schools in Brooklyn and Queens, New York. Schools were assigned noise exposure scores based on Noise Exposure Forecast contours for New York City airports. The correlations between these noise scores and a variety of noise level metrics ranged from 0.74 to 0.97. The regression coefficients adjusted for confounding factors, indicated that an additional 3.6% of the students in the noisiest schools read at least 1 yr below grade level with 95% confidence limits from 1.5 to 5.8%. The dose-response relationship indicated that the percent reading below grade level increased as noise level increased.

SEVERAL STUDIES have examined the effect of exposure to high levels of environmental noise on children's reading ability. Cohen et al.¹ found that elementary school students living for at least 4 yr on the lower floors of an apartment complex above a heavily trafficked bridge in New York City showed greater impairment of reading ability than those living on higher floors. Indoor noise levels varied from 66 decibels (dB) on the lower floors to 55 dB on the higher floors. When differences in parental education level were controlled, however, the correlation between floor level and reading test scores was reduced to marginal statistical significance in the 54 students tested. No effect was observed in children living in the complex

for less than 4 yr, suggesting that the effect resulted from chronic noise exposure.

Bronzaft and McCarthy² found a statistically significant decrease in mean reading test scores of elementary school students whose classrooms faced an elevated subway line compared to pupils in the same school whose classrooms faced quiet streets. Noise levels increased to 89 dB whenever an elevated subway train passed by, but on the quiet side the noise level remained at 59 dB. Classrooms did not differ in overall intellectual or achievement level and pupil assignment to classrooms was random. However, the possibility that the observed differences in reading test scores were due to noise distraction while the students were taking the test was not eliminated.

Maser et al.³ reported that children who attended school under the Seattle-Tacoma airport flight paths showed a deficit on standardized tests of scholastic achievement compared to students in quiet schools. The deficit increased as the students continued in the noisy schools, becoming statistically significant by the seventh grade. The deficit was evident within groups of students divided into thirds based on their initial academic aptitude. However, other differences between the schools, such as teacher training or ability, racial composition, and socioeconomic level of the student body were not controlled.

Cohen et al.⁴ reported that reading and math test scores of third grade students in noise-abated classrooms were higher than those in classrooms without noise abatement after adjusting for race, number of months in school, and mean cognitive ability of the class measured in the first grade. Only the differences in the math test scores were

statistically significant. Students in the noise-abated classrooms, however, also scored higher than students in quiet classrooms in schools far away from the Los Angeles International Airport, the source of noise in this study. These quiet schools were in a different school district, and the authors believed that the different administration policies, quality of teaching, and level of Federal aid were more important than noise exposure in affecting performance on reading and math tests.

In summary, these studies suggest that elementary school students who live and attend school in noisy environments have reduced scores on reading tests. However, these studies have examined only a few selected schools and they have not examined the effects of different levels of noise exposure on reading ability. This study was designed to answer these objections. This study utilizes the vast amount of data on every school collected by the New York City Board of Education for several years and the published noise exposure contour maps for the major New York City airports. Multiple linear regression was used to control for confounding factors and to assess the significance of the noise exposure.

METHODS

Noise exposure estimation. Brooklyn and Queens elementary schools were divided into five groups based on Noise Exposure Forecast (NEF) contours for John F. Kennedy (JFK) and LaGuardia airports. Schools in each noise group were assigned a noise exposure score of 0, 1, 2, 4, or 8. Because of the large reduction in the size of the noise-impacted areas around JFK during the period under study, 1972-76, two sets of noise exposure scores were used. The first set, called the Noise 70 scale was based on 1970 contours for JFK⁵ and 1972 contours for LaGuardia.⁶ The second set, the Noise 78 scale, was based on 1978 contours for JFK⁷ and the same 1972 contours for LaGuardia. The criteria used to group the schools, the number of schools, and the noise exposure scores assigned to each group using the two noise scales are presented in Table 1.

Since the noise levels were not measured in the 362 schools, summary values from the long-term 24-hr noise measurements made by the Federal Aviation Administration⁸ and by Tom O'Hare of the Environmental Protection Agency (personal communication, 1978) were compared with the noise scores assigned to the measurement locations to examine the validity of the noise scales. Since the noise

scales were designed to measure only the relative noise exposure levels of the different schools, the product moment correlation between the noise scores and the noise levels is an appropriate measure of agreement. The results, presented in Table 2, indicate good agreement between the noise scales and a variety of noise level metrics. The correlations with the Noise 78 scale ranged from 0.81 to 0.97 and the correlations with the Noise 70 scale were lower, 0.74 to 0.91, as would be expected since the noise measurements were taken between 1975 and 1978. Thus, the grouping of schools by the NEF contours and the assignment of noise scale values seem to have enough validity to justify their use in a preliminary study where the expense of obtaining more exact estimates of the noise level in each of the 362 schools would be prohibitive.

Reading test statistics and other data. A magnetic tape obtained from the New York City Board of Education contained the aggregate results of the annual nationally standardized tests of reading ability given in the New York City public schools and data on racial composition, socioeconomic level, and various educational factors for each school during the period 1972 to 1976. The dependent variables used in this study were the percent of students in each grade whose test scores placed them either 1 or more yr below grade level, or 2 or more yr below grade level. The independent variables taken from the tape include the percent of students in each of five ethnic groups, the percent eligible for free lunch programs, the absentee, admissions and departure rates, the pupil-teacher ratio, the percent of teachers with 5 or more yr experience, and the percent of teachers on two pay scales which reflect the amount of post-baccalaureate education. The data for these variables were based on the entire school with the exception of the racial composition data which were specific for each grade after 1973. The means and standard deviations of the variables used in the regressions are presented in Table 3. As an example of the distribution of the dependent variables, Figure 1 presents a histogram of the percent of fourth grade students reading 1 or more yr below grade level.

The percent of students reading below grade level in each grade was regressed on the independent variables for each of the years 1972 to 1976 and for all 5 yr combined. The data from each school were weighted proportionally to the number of students who took the reading test. Regressions using the combined 5-yr data included indicator variables for the different years to allow for temporal

§C6 salary schedule reflects more than 60 hr post-baccalaureate education.

#C1 salary schedule reflects less than 30 hr post-baccalaureate education.

changes in the mean reading level. Squared, square root, and interaction terms for the percent Black, percent Puerto Rican, and the percent eligible for free lunch programs were included in the regressions to remove abnormal trends in the plots of residual values against these variables.

The relationship between the level of aircraft noise exposure and the percent reading below grade level, the dose-response relationship, was examined by regression analysis using indicator variables for each of the noise level groups instead of a single variable with the noise scale val-

ues. This method of analysis is explained further in the Appendix.

RESULTS

Noise scale variable coefficients. The partial regression coefficients for the noise scale variables (b), their two-tailed level of statistical significance (P value) and the square of the multiple correlation coefficient (R^2) are presented in Table 4 for the regressions using the combined 5-yr data. All of the coefficients are positive, indicating that

* b = Partial regression coefficient.
 † P Value = two-tailed level of statistical significance.
 ‡ R^2 = Square of the multiple correlation coefficient.
 §NS = Not statistically significant.

the percent reading below grade level was higher in the noise-exposed schools. The coefficients were statistically significant at the .05 probability level in 15 of 18 regressions.

The coefficients from the regressions of the percent reading 1 or more yr below grade level range in magnitude from 0.263 to 0.926. By weighting each of these coefficients proportionally to the average number of students in that grade and inversely proportional to the variance of the coefficient, a summary coefficient of 0.62 with 95% confidence limits of 0.51 to 0.74 can be obtained.⁹ Since regression coefficients estimate the average change in the dependent variable that accompanies a one unit change in the independent variable, this coefficient suggests that a one unit increase in noise score would be accompanied by an increase of 0.62% in the number of students reading 1 or more yr below grade level in an average school.

The coefficients from the regressions using yearly data, which are not shown, were occasionally negative (11 of 90). Forty-one coefficients, all positive, were statistically significant. For the last 3 yr of the study, for which grade-specific racial composition data were available, all the coefficients were positive and 37 of 54 were statistically significant. These coefficients were of similar magnitude within each combination of grade, reading test statistic, and noise scale, indicating stability in the estimates of the effect of noise using data from different years.

Dose-response relationship. The difference in the percent reading 1 or more yr below grade level in the various noise exposure groups, as extrapolated from the indicator variable coefficients, is presented in Figure 2 along with a dotted line representing the linear dose-response relationship assumed by the use of the noise scale. The increase

in the indicator variable coefficients with increasing noise score was statistically significant indicating that the percent reading below grade level increased with increasing noise level. Although the percent reading below grade level appears to be higher than the linear dose-response relationship at moderate noise levels, and less than the linear relationship at high levels, tests of the goodness of fit, described in the Appendix, indicated that there was no significant improvement when the indicator variables were used rather than the noise scale variable in three of four

Fig. 2. Dose-response relationship between aircraft noise scale values and the difference in the percent reading below grade level in the noise scale zero group of schools and each of the other groups. Point estimates and 95% confidence limits for the effect at each level are plotted along with a dotted line representing the linear dose-response relationship assumed by the use of the noise scale values.

regressions. Thus, the data are largely compatible with a linear dose-response relationship.

The actual level of reading impairment in the different noise exposure groups can be directly estimated from the dose-response curve. The mean difference in the percent reading 1 or more yr below grade level in the noisiest schools, those within the NEF 40 contour, compared to the quietest schools, outside the NEF 30 contour, is 3.6% with 95% confidence limits from 1.5% to 5.8%.

DISCUSSION

Several limitations of this study need to be considered: (1) the noise exposure scale, (2) pupil transfers, (3) the variables used to control confounding, and (4) the aggregate nature of the statistics.

Although we do not know whether the effect of noise on reading ability is best related to the noise energy level, peak noise level, the amount of time the noise is above a certain level or some other metric, the noise scale used in this study correlated well with a variety of noise metrics. Thus it is doubtful that the use of another metric within the noise contours generated from it would result in a substantially different division of schools into noise groups. The results would, therefore, be similar if another noise scale were used.

The average noise exposure of all the students in a school zone is derived from local and domestic noise sources as well as aircraft. Examination of neighborhood noise contours¹⁰ indicated that the effects of local noise sources, such as elevated subway trains and heavily trafficked streets, were greatly reduced only a few blocks from the source. Thus it is doubtful that these noise sources would substantially alter the average noise exposure for all the students. Domestic noise exposure could not be directly estimated, therefore the results of this study depend on the assumption that this factor does not substantially confound the analysis.

Although elementary schools draw the vast majority of their pupils from the immediate neighborhood, transfers are allowed for a variety of reasons. If poor readers tended to transfer from noise-exposed schools into nonexposed, the noise variable coefficients would be decreased. Analysis of such transfers indicated that more poor readers transferred into nonexposed schools than would be expected from the percent of all students in nonexposed schools.¹¹ However, the number of such transfers, about 2% of the school population was too small to greatly affect the regression coefficients. Transfers of minorities for purposes of racial balance have also generally been from noise-exposed to nonexposed areas. These transfers would also tend to decrease the magnitude of the noise variable coefficients because these students, who are likely to be poor readers, are counted in the nonexposed schools although they live in noise-exposed areas. Thus, due to transfers, the noise variable coefficients would tend to underestimate the effects of noise on reading ability; however, the bias would probably be small.

Although this study includes adequate measures of many factors which affect reading ability, the only variable which directly measures the important factor of socioeconomic status is the percent of students eligible for free

lunch programs, the number of low income families. The racial composition variables are also highly correlated with socioeconomic status, and the use of squared, square root and interaction terms allows the model to accommodate nonlinear effects of these variables. Although it is doubtful that additional measures of socioeconomic level, such as parental occupation or educational level, would alter the results, they would be useful to demonstrate the adequacy of control over this important factor.

It is possible that there are other factors strongly correlated with both noise levels and reading ability and which would, therefore, affect the noise variable coefficients. However, an examination of maps constructed from basic racial, socioeconomic, educational, and residential data from the 1970 census¹² failed to reveal any factors which were strongly correlated with the noise contours around both airports. Census data were not included in the regressions because there are often considerable differences between the general population in a census tract and the families from that tract that have children in the public schools.

The major limitation of this study is the aggregate nature of the statistics which preclude examination of individual reading ability. Factors which affect the percent reading below grade level may not have the same effect on individual reading ability. To measure the effect of noise on individual reading ability, it would be necessary to relate each student's noise exposure from all sources to the student's reading test scores controlling for race, socioeconomic level, and other confounders. Such a study is recommended.

†Mean sq error = mean square due to error.

‡Two Plus = the percent of students reading 2 or more yr below grade level.

§P Value = probability level.

#One Plus = the percent of students reading 1 or more yr below grade level.

CONCLUSIONS

Although the conclusions of this study must be qualified because of the less-than-ideal measures of noise exposure and socioeconomic level that were available and the aggregate nature of the statistics, the results support the hypothesis that high levels of environmental noise are inversely related to reading ability in elementary school children. The regression coefficients indicate that an additional 3.6% of the students in the noisiest schools read at least 1 yr below grade level with 95% confidence limits from 1.5% to 5.8%. The dose-response relationship suggests that the percent reading below grade level increases with increasing noise level.

The Environmental Protection Agency estimates that 15% of the U.S. population is exposed to average noise levels above 65 dB and 1.5% is exposed to levels above 75 dB¹³ which are roughly equivalent to the noise levels at the NEF 30 and 40 contours, respectively. Since this study and others suggest that some children exposed to these noise levels would have decreased reading ability, additional studies are necessary to determine more precisely the extent of the reading impairment at environmental noise levels.

APPENDIX

The use of indicator variables to estimate the dose-response relationship is similar to using analysis of covari-

ance to estimate the effects of different levels of a non-metric factor (the noise exposure groupings) while adjusting for all the other variables listed in Table 5. Four indicator variables were used to code for each group of schools, using the schools assigned a noise score of zero as the reference group. All four indicator variables were given a value of zero for these schools in the reference group. Each of the other groups of schools had an indicator variable which was assigned a value of one for that group and zero for the other three. Thus the first indicator variable was coded zero for all schools except those assigned a noise scale value of one.

The coefficient for each indicator variable from the multiple regression analysis estimates the mean difference in the percent reading below grade level between the schools coded for by that indicator variable and the reference group, adjusted for the effects of the other variables. For example, the coefficient for the first indicator variable from a regression of the percent of fourth graders reading 2 or more yr below grade level was 0.867 (not given elsewhere in this paper). Thus, 0.867 was the average difference in the percent reading below grade level between schools with a noise score of one and those with a noise score of zero on the Noise 78 scale.

To combine this estimate of the effect of noise in that group of schools with estimates from other regressions, it was necessary to take into account the differences in the coefficients that result from using different grades and reading test statistics. These differences were eliminated by dividing the indicator variable coefficients by the noise scale variable coefficient obtained from regression on the same data. This standardized ratio expressed the change in reading ability in multiples of the noise scale variable coefficient. In this example, the noise scale variable coefficient was 0.688, as given in Table 4, and the ratio was 0.867/0.688, or 1.26.

The standardized ratios and the weighted averages for each noise scale group are presented in Table 6. Since these ratios are not as readily understood as the percent reading below grade level, the averages were transformed back into the latter by multiplying each by the summary noise scale variable coefficient, 0.62, for Figure 2. Thus, in the highest noise scale group, the weighted average of the noise scale variable coefficient was 5.9 which when multiplied by the summary noise scale variable coefficient, yields the estimate that an additional 3.6% of the students in an average-sized school in the noisiest zone would read at least 1 yr below grade level compared to schools in the quietest area.

In addition, the degree to which the regression model with the indicator variables fits the data better than the model with the noise scale variable can be determined from the difference in the sum of squares due to regression for each model. This difference divided by the number of additional parameters used, 3, and by the mean square due to error can be tested against the *F* distribution to determine the probability that chance alone could account for the difference in the sum of squares. The results, presented in Table 7, indicate that chance could easily account for the differences in the goodness of fit in all but one case.

Further details on the use of indicator variables in regression analysis can be obtained from several textbooks.^{14, 15}

Research Report

A PROSPECTIVE STUDY OF SOME EFFECTS OF AIRCRAFT NOISE ON COGNITIVE PERFORMANCE IN SCHOOLCHILDREN

Staffan Hygge,¹ Gary W. Evans,² and Monika Bullinger³

¹Centre for Built Environment, University of Gävle, Gävle, Sweden; ²Department of Design and Environmental Analysis and Department of Human Development, Cornell University; and ³Department for Medical Psychology, University of Hamburg, Hamburg, Germany

Abstract—Before the opening of the new Munich International Airport and the termination of the old airport, children near both sites were recruited into aircraft-noise groups (aircraft noise at present or pending) and control groups with no aircraft noise (closely matched for socioeconomic status). A total of 326 children (mean age = 10.4 years) took part in three data-collection waves, one before and two after the switch-over of the airports. After the switch, long-term memory and reading were impaired in the noise group at the new airport, and improved in the formerly noise-exposed group at the old airport. Short-term memory also improved in the latter group after the old airport was closed. At the new airport, speech perception was impaired in the newly noise-exposed group. Mediational analyses suggest that poorer reading was not mediated by speech perception, and that impaired recall was in part mediated by reading.

A consequence of modern means of transportation is widespread noise exposure. In Europe, almost 25% of the population is exposed to equivalent noise levels (L_{eq}) of 65 dBA or more (Berglund & Lindvall, 1995). At this level, annoyance is marked, sleep is disturbed, and some cognitive processes are impaired (Cohen, Evans, Stokols, & Krantz, 1986; Evans & Lepore, 1993; Smith & Jones, 1992). Noise exposure is consistently correlated with reading deficits and may interfere with speech perception and long-term memory in primary-school children (Evans & Lepore, 1993).

The simultaneous opening and closing of the new and former Munich Airport provided us with an unprecedented opportunity to conduct a prospective study of the effects of aircraft noise on children. This is the only prospective study of nonauditory effects of noise on children that has been undertaken. Moreover, cessation of noise at the old airport provided a unique opportunity to assess whether expected, noise-related impairments are reversible. Sociodemographically matched control groups exposed to little aircraft noise were formed at both airports. By testing the children in silence and not in everyday-noise settings, we eliminated confounds between chronic versus acute noise. Furthermore, examination of the interplay among attention, memory, and reading over time enabled us to test whether expected noise-related reading deficits could be accounted for by shifts in underlying cognitive processes.

Previous cross-sectional research (Cohen et al., 1986; Cohen, Glass, & Singer, 1973; Evans & Maxwell, 1997) indicated that noise-related reading deficits might be mediated by a cognitive strategy wherein children become less attentive to auditory stimuli as a way to cope with noise. It is unclear whether such shifts in attentional strategies are general to noise

or specific to speech. Laboratory noise also impairs both long-term memory (Hygge, 1997; Hygge, Boman, & Enmarker, in press) and short-term memory (Hamilton, Hockey, & Rejman, 1977; Hockey, 1979). Both speech perception and memory are related to reading acquisition (Crowder & Wagner, 1992; Mann & Brady, 1988).

In summary, we collected prospective data to assess how children's reading was affected by changes in ambient noise levels caused by modified airport operations. In addition, we investigated two cognitive processes, attention and memory, implicated in prior experimental work on acute noise exposure, and how they relate to speech perception.

METHOD

Design and Subjects

The two experimental groups comprised children who were (old airport) or would be (new airport) exposed to aircraft noise. The two control groups were selected from areas that had little exposure to aircraft noise. The control groups were matched with their respective experimental groups on the basis of sociodemographic characteristics. One wave of data collection started 6 months prior to the changeover of airports, the second wave was 1 year later, and the third wave 2 years later. A total of 326 children participated: 43 in the old-airport, no-noise group; 65 in the old-airport, noise group; 107 in the new-airport, no-noise group; and 111 in the new-airport, noise group. Their ages ranged from 8 to 12 ($M = 10.4$, $SD = 0.85$). The children at the new airport were tested 3 to 5 months before the children at the old airport, but there was no difference in average year of birth. Criteria for taking part in the study were a minimum of 2 years of residence and German fluency, which ruled out confounds with ethnicity. Normal hearing, as assessed by audiometric screening, was also a criterion for participation. The experimental and control groups at the two airports did not differ in age, gender, ethnicity, number of family members, parental occupation, or education, and attrition did not differ among the four groups, $\chi^2(3, N = 326) = 1.64, p > .10$.

Procedure and Materials

At each data-collection wave, the children were tested individually in silence for 1.5 hr on 2 consecutive days in a specially designed temperature-controlled and sound-attenuated mobile laboratory that traveled to their schools. The children worked individually on an array of different tasks. In this article, we present only the cognitive dependent measures. (For data on physiological stress and mental health, see Bullinger, Hygge, Evans, Meis, & von Mackensen, 1999; Evans, Bullinger, & Hygge, 1998; Evans, Hygge, & Bullinger, 1995.)

Aircraft Noise and Children

Reading

A standardized German reading test was employed (Biglmaier, 1969). The children read paragraphs and word lists of increasing difficulty. Some of the words in the lists were pseudowords, but phonologically appropriate in German.

Memory
